This listing of discernible amounts of federal funds used by the federal government for medical, hospital, health and allied purposes omits the budget estimate for the Medical Department, War Department, which for 1940 was \$1,601,072, and for the Bureau of Medicine and Surgery, Navy Department, which for 1940 was \$2,670,000, since it is recognized that the Army and the Navy require their own medical establishments.

The amounts authorized by and appropriated under authority of the Social Security Act (1935) for medical, hospital, health and allied purposes are listed under the agencies designated to administer the funds, viz. the Children's Bureau, Department of Labor and the Public Health Service, Treasury Department. Available sources provide no information as to whether other funds authorized by the Social Security Act are being utilized to provide some other forms of medical, hospital, health or allied services in addition to those for which funds are specifically designated.

It is likewise utterly impossible to arrive at an accurate current amount of expenditures for medical, hospital, health and allied purposes by all independent establishments, since the budget does not clearly indicate amounts for such purposes.

Some of the departments and independent establishments are engaged in activities which would seem to require some medical standards, personnel and services; many of these activities at least have an indirect public health significance. Available sources give no information of any federal funds designated for these purposes. The agencies which may be included in this category are the Bureaus of Air Commerce, Marine Inspection and Navigation, and the National Bureau of Standards in the Department of Commerce; the Bureau of Reclamation, the Bureau of Mines and the Columbia Institution for the Deaf in the Department of the Interior, the Departments of the District of Columbia charged with the general supervision and maintenance of mosquito control, sewers and sewage treatment, collection and disposal of refuse, public playgrounds and swimming and bathing pools, and the health phases of the public school program and the essential medical services required in connection with the District Training School, the Industrial Home for Colored Children and the Home for the Aged and Infirm. Among the independent establishments in this category are the Canal Zone and Alaska Railroad Retirement and Disability Funds, which are presumably required to determine the nature and extent of disability of those who apply for and are entitled to disability benefits administered by these agencies.

A report of the progress of the Works Progress Administration program issued as of the date of June 30, 1938, indicates that a total of \$105,454,328 was the total cumulative amount expended as of March 31, 1938, for sanitation and health, of which \$85,275,572 represented federal funds. It appears from the report that, among a considerable number of agencies engaged in the sanitation and health projects, close cooperation was secured from the U. S. Public Health Service.

It is impossible from the information that is available to tabulate accurately the amounts of emergency relief appropriations that were allotted to and expended by the U. S. Public Health Service or that were utilized by other agencies for medical, hospital, health or allied purposes. The Budget of the United States Govern-

ment does, however, contain reference to an allotment of \$1,506,338 from emergency relief appropriations to the Public Health Service for assistance for educational, professional and clerical persons for 1937; also an allotment of \$965,473 from the emergency relief appropriation of 1936 for the year 1937 for health and sanitation activities in flood stricken areas. It is not clear from the available information whether these items, which appear in the budget for 1939, are included in the cumulative total as of March 31, 1938, appearing in the tabulation on page 8 under Works Progress Administration. They have not been placed in the tabulation on the assumption that they may be included in the cumulative total as given in the Works Progress Administration report.

The Budget of the United States Government for 1940 contains an item under the Treasury Department, Public Health Service, for assistance for educational, professional and clerical persons, allotted from the emergency relief appropriation of 1937, of \$316,713 for 1938 and an item of \$179,432 received by transfer from the emergency relief and Works Progress Administration for similar purposes for the year 1939. These items are likewise omitted from the tabulations, since it is not clear in what year the allotments were made, and therefore they may be included in the cumulative total aforementioned.

In the Budget of the United States Government for 1939, an amount of \$162,138 was the estimated allotment to the U. S. Public Health Service from the emergency relief appropriation for 1935 for the Hot Springs Transient Medical Center Infirmary. The actual amount used for 1938 is given in the 1940 budget as \$156,023. In the 1939 budget an additional \$190,400 allotted to the Public Health Service from the emergency relief appropriation of 1937 for the Hot Springs Transient Medical Center Infirmary is listed as an estimate for 1938. This amount does not appear in the 1940 budget under the actual amounts used for 1938 for the same purpose. This \$190,400 does not appear in the accompanying tabulations, since the available information does not indicate what disposition was made of this allotment.

If therefore it was definitely known that the cumulative total given in the Works Progress Administration report did not contain the aforementioned items, the discernible totals would be increased by \$2,471,811 for 1937, \$316,713 for 1938 and \$179,432 for 1939. The 1937 total might be further increased by \$190,400 if the disposition of that amount could be determined.

The listed totals are therefore the nearest approximation that can be made from available sources of information. These approximations are underestimates, except for the Veterans' Administration, and would be increased if it were possible to obtain complete information from all federal agencies representing their total disbursements for all medical, hospital, health and allied activities.

The material contained with the tabulations and the explanations thereof was requested by the subcommittee of the Senate Committee on Education and Labor at the time of the hearings on the Wagner National Health Bill, at which the American Medical Association presented its statements on May 25 and 26, 1939. These tabulations and the accompanying explanations are offered for consideration of the subcommittee and inclusion in the record.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Changes in Status.—S. 2745 has been reported to the Senate, proposing to authorize the Commissioners of the District to promulgate and enforce all such reasonable rules and regulations as they may deem necessary to prevent and control the spread of communicable and preventable diseases in the District of Columbia. S. 2779 has been reported to the Senate, proposing to eliminate from the healing arts practice act of the District of Columbia the requirement that examinations be held on the second Monday in January and July of each year and to provide that such examinations may be held at such times as the Commission on Licensure to Practice the Healing Art may by rule or by special order determine. H. R. 4732 and H. R. 4733 have passed the House and have been reported to the Senate with recommendations that they pass, proposing respectively to provide for the issuance of a license to practice chiropractic in the District of Columbia to

George M. Corriveau and to Laura T. Corriveau. H. R. 6266 has passed the House and has been reported to the Senate, proposing to incorporate certain persons as Group Hospitalization, Inc. H. R. 7086 has passed the House and has been reported to the Senate, proposing to provide for insanity proceedings in the District of Columbia.

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 6555 has passed the House and has been reported to the Senate, proposing to amend the act relating to the advance of funds in connection with the enforcement of acts relating to narcotic drugs so as to permit such advances in connection with the enforcement of the Marihuana Tax Act of 1937. H. R. 6556 has passed the House and has been reported to the Senate, providing for the seizure and forfeiture of vessels, vehicles and aircraft used to transport narcotic drugs, firearms and counterfeit coins, obligations, securities and paraphernalia.

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

ARIZONA

The Arizona State Medical Association and the Arizona State Board of Health cooperated in sponsoring postgraduate instruction in obstetrics and gynecology in four cities of the state during 1938. Dr. Fred C. Jordan, chairman of the state association's committee on maternal and child health, which was composed of five members, represented the state association and conferred with the director of the Division of Maternal and Child Health of the Arizona State Board of Health. In February 1938 two out of state physicians conducted a series of lectures and discussions in pediatrics and obstetrics in two cities of the state. The instruction began at 5:30 p. m. with a lecture, then dinner, followed by a round table discussion after dinner and three lectures illustrated by movies, a total of twenty-four lectures in the series. Attendance averaged approximately fifty at each session. In May 1938 similar programs were given in obstetrics by another out of state obstetrician in two other towns. During 1939 five other localities will be visited and the more populous sections of the state will have been covered.

In the recent reorganization of the Arizona State Medical Association, the Committee on Maternal and Child Health was made a standing committee with the present three members serving one, two and three years, respectively. Dr. C. B. Warrenburg is temporary chairman of this committee. Another newly created standing committee concerned with scientific education and postgraduate activities has three members, with Dr. F. W. Butler as chairman. Other committees having interest in continuing professional instruction include the committees on scientific assembly, industrial health, syphilis and social diseases, cancer, orthopedics and tuberculosis.

The Southwestern Medical Association was formed twenty-five years ago and its membership includes licensed reputable physicians in Arizona, New Mexico, western Texas and northern Mexico. The annual conference of the association, held each October or November in either Arizona or Texas, is devoted to advancing medical training. Until six years ago local physicians participated with few visiting lecturers. At present ten or twelve guest speakers participate each year and discuss subjects of their own selection. The attendance has averaged from 160 to 180 each year. Approximately 100 physicians come from Texas, thirty from Arizona and the remainder from New Mexico and from Mexico. A registration fee of \$5 is charged for the three day clinical conference. Commercial exhibits aid in financing the program.

There are 562 licensed physicians in the state, of whom 356 are members of the Arizona State Medical Association.

WEST VIRGINIA

In 1936 the West Virginia Medical Association with the cooperation and financial aid of the state health department offered practicing physicians of the state postgraduate instruction in pediatrics. The state association's committee on maternal welfare, which includes a member from each council district, and the committee on child hygiene, likewise constituted, acted in an advisory capacity to the health department. The chairman of each committee and the director of the bureau of child hygiene conferred regarding a program, but during the first two years direction and administration was largely by the health department.

Instruction in pediatrics was offered in fifteen cities and larger towns during the first year by a West Virginia pediatrician. Lectures were given the same day each week for six times on a circuit plan. Pediatrics was considered first because of the desire to reduce infant mortality in the state, to stress the need for antepartum care and to prepare for the instruction in obstetrics which was proposed for 1937. About 170 physicians registered for the 1936 postgraduate course.

During July and August 1937 five lectures were given in ten other cities and towns of the state. Two out of state obstetricians gave a total of three lectures in obstetrics in each locality and two out of state pediatricians gave two lectures in pediatrics. Instruction was offered at weekly intervals following the circuit plan. Approximately 280 physicians attended these courses in 1937.

As a result of the experience of the first two years and of the desire on the part of the members of the state association's committees to create greater interest in postgraduate study, the state health department agreed to allow the state medical association to administer the postgraduate courses during 1938. Under this plan the state association took a more active part in promoting the courses and in procuring the sponsorship of the county medical societies. With the financial assistance of the health department, the employment of competent instructors was assured. The office of the executive secretary was responsible for the direction and administration of the teaching program. The committee on infant and maternal welfare of the state association, consisting of the chairmen of the committees on maternal welfare and on child welfare and the director of the bureau of child hygiene of the state health department, offered the county societies of the state the resources of the committee. Two circuits were planned with eight towns in each in the rural sections of the state. Since these county societies represent sections of the state not previously covered, it is probable that by the end of this year all parts of the state will have been visited. Four out of state instructors have been

secured. The first three lectures in each locality will be devoted to obstetrics and the last two to pediatrics. It is anticipated that the physicians who could not attend the courses given in previous years will avail themselves of the state association's

present program. Approximately 150 have registered. No registration fees have been charged since 1936.

There are 1,823 physicians licensed in the state, 1,240 of whom are members of the West Virginia State Medical Association.

MEDICAL ECONOMIC ABSTRACTS

PREVENTIVE MEDICINE IN CHILE

The following are summaries of two articles by Dr. Carlos Maldonado B., director of medical services of the Department of Compulsory Insurance, on medical-social laws recently passed in Chile, which appeared in the *Boletín medico social de la caja de seguro obligatorio* (5:281 [Aug., Sept., Oct.], 414 [Nov., Dec.] 1938).

THE LAW 6174

The Law 6174, or the Cruz Coke Law, on preventive medicine is believed to be one of the most important social-economic laws promulgated in the last few years in Chile. This law is of great importance to the Department of Compulsory Insurance, which is interested in preventive medicine as one of the means of avoiding the high cost of morbidity. It brings out the true importance of health examinations which makes it possible to discover and treat illnesses most effectively. For example, among the supposedly healthy insured persons examined in factories it was discovered that 37.9 per cent needed medical attention. Of these 11.7 per cent had contagious diseases, 3 per cent tuberculosis and 5.1 per cent afflictions of the circulatory system. It was estimated that 60 per cent of the morbidity is due to illnesses of these three classifications and that they are also the cause of the greatest percentage of disability and death.

The law requires compulsory treatment for contagious diseases. This will permit early treatment of 10 per cent of the illnesses of working men which are the primary cause of disability among those now receiving disability compensation. Hitherto persons with contagious disease were treated only in the first period of illness and did not submit to further examination until the disease had produced disability. The number of infected persons who continued treatment until completely cured was about 8 per cent.

One of the most serious problems at present is the number of insured persons infected with tuberculosis. Of 8,090 deaths in 1936, 29.73 per cent were due to tuberculosis, and in 1937 of 8,511 deaths 31.18 per cent were caused by tuberculosis. Among the causes of disability it is in second place and caused 20.3 per cent of the disability in the last three years.

Previous to this law the disability compensation granted was so small that many infected persons continued working rather than submit to treatments. Under the earlier law compensation after the third week of disability was reduced to 25 per cent of the normal wage and the workman could not maintain himself and his family on such a reduced income. Therefore a large number of tuberculous patients would leave the sanatorium before they were completely cured, with the result that they would have to return again in a short time with a much smaller chance of complete recovery. The new law provides for a rest period for the tuberculous patient during which he is paid his total salary.

Infections of the circulatory system are the principal cause of disability, constituting 32.7 per cent. A considerable number of persons have some sort of infection of the circulatory system, as shown in examinations of supposedly healthy persons. Of those examined 5.1 per cent had defects of the circulatory system, of which about 10 per cent were so serious that the person should not be allowed to continue working. Until now nothing has been done in Chile to provide proper employment or medical treatment for persons with heart disease unless the person became seriously ill. Under this new law provisions are made for rest in a sanatorium and changes of occupation and residence, through the assistance of the Institute of Rehabilitation, which was created to deal with this problem.

RURAL SANITATION

The rural population of Chile makes up 52 per cent of the total population and therefore problems of rural sanitation are

of great importance. Although the density of the population is 5.6 per square kilometer, in reality the density is much greater because there are enormous stretches of uninhabited deserts.

Rural morbidity differs but little from urban, but the rural population is not as well protected from infectious diseases such as typhoid, scabies, chickenpox and venereal disease. The director of rural sanitation, because of limited resources, has aimed primarily toward health education in cooperation with municipal health organizations and has attempted to bring about improvements in respect to pure water, more sanitary toilets and control of infectious diseases, as in other countries.

The improvement of rural medicine should receive more attention from the Department of Compulsory Insurance, which has established medical facilities for its clients. These facilities consist of 164 rural medical stations and 365 distributing centers throughout the country. Doctors in nearby cities spend certain days or hours in the distributing centers, during which time the insured persons may obtain medical services. The rural medical stations do not have a medical officer in residence but are attended by the personnel from the nearest distributing center, and certain doctors make periodic visits to these stations.

There are also forty-eight first aid stations with a doctor in charge and with beds for the hospitalization of emergency cases. These first aid stations not only provide curative medicine but also preventive medicine, such as antepartum care, obstetric care and medical care for children under 2 years of age, as well as treatment and control of contagious disease. Some of these stations have laboratories in order to facilitate diagnosis and treatment. The officers in these stations also try to educate the residents on the value of sanitation.

The rural housing problem is very serious. A large part of the rural population live in inadequate and insanitary houses and do not practice the most elementary principles of hygiene. The governor obtained from the national congress permission to establish a department of housing the purpose of which is to encourage the building of low cost houses for laborers, farmers and their families. This department is directed by the minister of labor and received an appropriation of \$4,000,000 to be used for the following purposes:

1. Construction of houses under the direction of the department.
2. To make loans for buildings.
3. The urbanization of industrial districts constructed before this law was passed.
4. To encourage the raising of home produce and the development of domestic industries.

This law makes it especially easy for the proprietors of large farms to obtain loans at low interest, which are to be used exclusively for the construction of houses for their tenants. The borrowers are compelled to construct homes according to the law, which established severe penalties for any infractions. In order to encourage such building the department will lend about \$360 for each house. A permanent commission of housing is directly under the director general of sanitation and is requested to consult with engineers, doctors, scientific institutions and other organizations in regard to the construction of houses and the disposal of waste and sewage.

The farmers have looked forward to the application of this law, which was passed in February 1937, and have given it their support. In the province of Santiago a Farmers' Union was organized for the purpose of cooperating in the construction of houses and to bring about improvements in rural health sanitation. No important results will be observed at once, but this plan in conjunction with the social security plan under the minister of health should bring rapid improvement in the medical and social conditions in this country.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—Dr. William L. Miller, Gadsden, discussed food allergy before the Etowah County Medical Society June 20 at a meeting in Gadsden.—Dr. John C. Burch, Nashville, Tenn., discussed "Medical and Surgical Treatment of Menstrual Disorders" before the Calhoun County Medical Society in Anniston May 23.

Personal.—Dr. Jephtha W. Dennis, Montgomery, has been appointed college physician and director of the student health service at the Alabama Polytechnic Institute, Auburn, effective September 1. He will succeed Dr. Benjamin F. Thomas, who has resigned to devote his full time to the practice of medicine in Auburn.

CALIFORNIA

Hospital News.—Ground-breaking ceremonies for the first unit of the Mount Sinai free medical clinic in Los Angeles were held June 25. The \$250,000 unit will be dedicated to charitable service without question of creed, race or color.—Dr. Burton W. Adams, Oakland, has been appointed superintendent of the San Diego County Hospital, San Diego.

Changes in the Faculty at California.—Recent promotions on the staff of the University of California Medical School, San Francisco, include:

Dr. Israel L. Chaikoff, to be associate professor of physiology.
Paul L. Kirk, Ph.D., associate professor of biochemistry.
Dr. Amos U. Christie, associate professor of pediatrics.
Dr. William C. Deamer, associate professor of pediatrics.
Dr. Dudley W. Bennett, associate clinical professor of medicine.
Dr. Myrl Morris, associate clinical professor of pediatrics.
Dr. M. Laurence Montgomery, associate clinical professor of surgery.

Dr. Walter L. Treadway, U. S. Public Health Service, has been appointed lecturer in psychiatry and Dr. Olga L. Bridgman, professor of pediatrics and psychology, has been granted a sabbatical leave of absence from January to June 1940.

COLORADO

Society News.—The Washington-Yuma County Medical Society was addressed July 3 in Wray by Drs. Roderick J. McDonald Jr., Denver, on "Streptococcal Infections" and Jack G. Hutton, Denver, "Dermatologic Conditions and Their Treatment."—At a meeting of the Northeast Colorado Medical Society, Sterling, June 8, Dr. Henry A. Buchtel, Denver, discussed "The Place of the Urologist in the Practice of Medicine."—The Delta County Medical Society was addressed in Delta recently by Dr. Robert A. Underwood, Delta, on hypertension.

CONNECTICUT

Personal.—Dr. John D. Milburn, East Hampton, has resigned as medical examiner and announced his retirement from active practice. He will be succeeded as medical examiner by Dr. Norman H. Gardner.

Changes in Health Officers.—Dr. Albert E. Childs, Litchfield, has been appointed health officer for the borough of Bantam, according to the *Connecticut Health Bulletin*. Other changes noted include:

Dr. Noah A. Burr of Haddam.
Dr. Charles E. McPartland of West Hartford, succeeding Dr. Harry B. Smith.
Dr. Frederick B. Dart of East Lyme to complete the unexpired term of the late Dr. Frederick H. Dart.
Dr. Albert J. Trimpert of Redding to succeed the late Dr. Ernest H. Smith.

DISTRICT OF COLUMBIA

Committee on Automobile Accidents.—At the annual business meeting of the Medical Society of the District of Columbia, Washington, May 3 the establishment of a committee on automobile accidents was authorized to study the accident situation from the medical standpoint and to cooperate with the traffic advisory council of Washington. This action was taken after a request had been received from the council asking the society's cooperation in an educational campaign to prevent a recurrence of the child traffic fatalities of last summer, according to the *Medical Annals*. Statistics from the

safety and traffic engineering department of the District of Columbia Motor Club show that of 821 fatality victims in the District from Jan. 1, 1931, to Nov. 30, 1938, 579 were pedestrians. During the period twenty-seven pedestrians were injured to every pedestrian killed. An analysis shows that the fatalities of this group increase sharply after the age of 50 and that the hazard is much greater by night than by day. During the period from 1931 to 1938, 106 children were killed in traffic and in 1938 alone 888 child pedestrians suffered injuries. Members of the new committee are Drs. William Warren Sager, chairman; Edgar Leonard Goodman, Paul J. O'Donnell, Morris I. Bierman and Herbert S. Gates.

FLORIDA

State Law Regulates Drug Prescriptions.—Five dangerous drugs may be dispensed only on a written prescription signed by a duly registered physician, dentist or veterinarian in accordance with one section of the new state food, drug and cosmetic act which went into effect July 1. The drugs are aminopyrine, barbituric acid, cinchophen, dinitrophenol and sulfanilamide.

Members of Medical Board.—Dr. Samuel G. Hollingsworth, Bradenton, was named president of the Florida State Board of Medical Examiners at its semiannual meeting June 20 and Dr. Benjamin A. Chapman, Jacksonville, vice president. Dr. William M. Rowlett, Tampa, was reelected secretary. Other members of the board include Drs. Harold D. Van Schaick, Jacksonville; Julius C. Davis, Quincy; James E. Crump, Winterhaven; Horace A. Day, Orlando; Thomas W. Hutson, Miami; Corbett E. Tumlin, Miami, and Carl A. Williams, St. Petersburg.

IDAHO

Society News.—A recent meeting of the North Idaho Medical Society in Lewiston was addressed by Drs. James W. Mounsey and Robert G. Boyd, both of Spokane, Wash., on various types of malignancy and cervicitis, respectively.—The South Side Medical Society was addressed in Burley recently by Drs. Kenneth B. Castleton on "Duodenal Surgery" and Richard P. Middleton, "Renal Surgery"; both are from Salt Lake City.

INDIANA

Postgraduate Conference on Obstetrics.—The Grant County Medical Society conducted a postgraduate conference on obstetrics at the Marion General Hospital, Marion, June 13-15. Cooperating with the society were the committee on postgraduate education of the Indiana State Medical Association, the department of postgraduate education of the Indiana University School of Medicine and the bureau of maternal and child health of the state board of health. Dr. Carl P. Huber, resident adviser and research director in obstetrics and gynecology, Indiana University School of Medicine, Indianapolis, was in charge. This conference is the first of scheduled programs of postgraduate education to be carried to selected areas throughout the state.

IOWA

Twin Lakes District Meeting.—A dry diagnostic clinic, comprising the sixteenth annual assembly of the Twin Lakes District Medical Society, was held at Rockwell City June 15. The participants were:

Dr. Harold C. Habein, Rochester, Minn., Medical Emergencies.
Dr. August A. Werner, St. Louis, Endocrinology.
Dr. William P. Wherry, Omaha, Otolaryngology.
Dr. Italo F. Volini, Chicago, Medicine.
Dr. Michael L. Mason, Chicago, Surgical Emergencies.

Dr. Louis B. Wilson, Rochester, Minn., presented an address entitled "The Education of a Doctor" and Dr. Ernest E. Shaw, Indianola, chairman, medical economics committee, state medical society, presided at a round table on medical economics.

KENTUCKY

New Health Officers.—Dr. Frank Kash Sewell, Madisonville, has been appointed health officer of Breathitt County. Dr. Andrew B. Colley, Tompkinsville, has been appointed health officer of Webster County to succeed Dr. Charles M. Smith, Dixon, resigned.

Society News.—Drs. George K. Carpenter and David W. Hailey, Nashville, Tenn., addressed the Christian County Medical Society, Hopkinsville, June 20, on "Relationship of Syphilis to Bone Trauma" and "Management of Nephritis" respectively.—Drs. John B. Youmans and Rudolph H. Kampmeier, Nashville, addressed the Hopkins County Medical

Society, Madisonville, June 6 on "Practical Aspects of Vitamin Deficiency" and "Clinical Aspects of Lymphogranuloma Venereum" respectively. — At a meeting of the Eleventh Councilor District of the Kentucky State Medical Association in Harlan recently the speakers were Drs. Maurice G. Buckles on "Modern Concepts of Pulmonary Tuberculosis"; Harry S. Andrews, "Treatment of Pneumonia in Children," and Irvin Abell Jr., "Empyema." All are of Louisville. — Dr. Paul A. Turner, Louisville, was named president-elect of the Kentucky Hospital Association at the recent annual meeting and Dr. Edward J. Murray, Lexington, became president.

LOUISIANA

Society News.—The Orleans Parish Medical Society held a clinical meeting at the U. S. Marine Hospital June 26; the speakers were Drs. Joseph G. Pasternack on "Hodgkin's Disease, an Experimental Study of the Etiology" and John A. Trautman, "Lymphogranuloma Inguinale: Treatment with Sulfanilamide, and by Pyretotherapy." — The Lafourche Valley Medical Society was addressed June 21 by Drs. Henry C. Dansereau, Labadieville, on "Preventive Medicine: A Plea for Its Greater Popularization by the General Practitioner"; Louis A. Monte, New Orleans, "Treatment of Acute Disorders Due to Some of the Chemical and Physical Agents," and Edgar Hull, New Orleans, "Remediable Factors in Heart Disease."

Personal.—Dr. Wilbur C. Smith, professor and head of the department of gross anatomy, Tulane University of Louisiana School of Medicine, New Orleans, and athletic director of the university, received an honorary degree of doctor of science from Wake Forest College, Wake Forest, N. C., at the recent commencement exercises. Dr. Smith was head of the department of anatomy at Wake Forest for three years prior to coming to Tulane. — Dr. Emmett L. Irwin has been named head of the health and safety committee of the New Orleans Area Council, Boy Scouts of America. This committee is planning a program for the education of scouts in safety skill and health practices and the rendering of service in time of emergency and disaster.

MARYLAND

Dr. Barker Named Assistant Dean.—Dr. William Halsey Barker, instructor in medicine, Johns Hopkins University School of Medicine, Baltimore, has been appointed assistant dean of the medical school. In this newly created position he will aid Dr. Alan M. Chesney, dean, chiefly in the field of student relations. He will also serve as a member of the committee on admissions of the medical school. Dr. Barker graduated at Johns Hopkins in 1932. He is the son of Dr. and Mrs. Lewellys F. Barker, Baltimore.

Association of Laboratory Workers.—The Maryland Association of Medical and Public Health Laboratories has been organized to collaborate with official agencies in the development of effective routine laboratory procedure. Membership is open to all who are either directly or indirectly engaged in such work in the state. The executive council of the association is composed of the president, Mr. Edward G. Gummell, Silver Spring; Dr. Albert A. Pearre, Frederick; the secretary-treasurer, Miss Florence R. Hill, 402 Compton Avenue, Laurel; Dr. Harry Eagle, Baltimore, and Dr. Ira A. Darling, Sykesville.

MASSACHUSETTS

Memorial to Dr. Hawes.—The Boston Tuberculosis Association announces plans to establish a memorial to the late Dr. John B. Hawes 2d, formerly president of the association. A memorial in the form of a fund to sponsor an annual lecture in tuberculosis is under consideration. Prior to his death in 1938, Dr. Hawes had served, among other things, as director of the Rutland Cottage Sanatorium, Rutland, and consultant in diseases of the lungs to the U. S. Veterans' Administration. He had written extensively on pulmonary diseases.

Personal.—Dr. Hans Zinsser, Charles Wilder professor of bacteriology and immunology, Harvard Medical School, Boston, received the honorary degree of doctor of science from Yale University at the recent annual commencement in New Haven. — The degree of doctor of science was conferred on Drs. Joseph Emmons Briggs, Boston, and William O. Faxon, Stoughton, Mass., by Boston University School of Medicine at the annual commencement June 12. Both physicians are graduates of the school. Dr. Faxon is said to be the oldest living graduate of the school of medicine. — Dr. George B. Wislocki, Parkman professor of anatomy, Harvard Medical School, has been appointed an associate editor of the *American Journal of Anatomy*.

MICHIGAN

Upper Peninsula Meeting.—The Upper Peninsula Medical Society will hold its annual meeting in Escanaba August 23-24. The state medical journal prints the following tentative program:

Dr. Henry F. Helmholz, Rochester, Minn., Urinary Tract Infections in Children.
Dr. Leo G. Christian, Lansing, Serum Treatment of Pneumonia.
Dr. Francis D. Murphy, Milwaukee, Problems in Clinical Medicine.
Dr. William E. Blodgett, Detroit, First Aid Treatment of Fractures.
Dr. Henry R. Carstens, Detroit, Peripheral Vascular Disease.
Dr. Horton R. Casparis, Nashville, Tenn., Tuberculosis.
Dr. John T. Murphy, Toledo, Ohio (subject not announced).

Dr. William W. Bauer, Director, Bureau of Health Education, Chicago, will speak at the banquet August 23 on "Popular Beliefs That Are Not So."

Appointments to Wayne University.—Frederick F. Yonkman, Ph.D., formerly associate professor of pharmacology at Boston University College of Medicine, Boston, has been appointed professor of pharmacology and therapeutics and head of the department at Wayne University College of Medicine, Detroit, according to an announcement. Dr. Arnold J. Lehman, formerly instructor in pharmacology at Stanford University College of Medicine, San Francisco, and recently assistant professor of pharmacology at George Washington University Medical School, Washington, D. C., has been appointed research associate in pharmacology and therapeutics with the rank of assistant professor. Dr. Harold F. Chase, formerly assistant in pharmacology, Boston University College of Medicine, has been appointed instructor in pharmacology. The promotion of Dr. Edgar H. Norris, professor of pathology (in charge of teaching), to be head of the department is also announced.

State Society Appoints Field Representatives.—The Michigan State Medical Society announces the appointment of field representatives in the various specialties of medicine and surgery as a part of the program of postgraduate education for physicians throughout the state. Drs. Alexander M. Campbell, Grand Rapids, and Clair E. Folsome, Ann Arbor, have been named field representatives in obstetrics and maternal health, and Dr. Clifford H. Keene, Ann Arbor, field representative in cancer. Later appointments in pediatrics and venereal diseases are being planned. Policies and plans of the representatives are arranged and supervised by a committee of the state medical society. The field representatives spend several weeks in a county to make available the latest advances in diagnosis and treatment in their special field of training. Their contacts are made only through organized county medical units, and their services consist of lectures, hospital staff conferences, personal interviews with physicians, small group conferences and informal association with the physicians at their request.

NEW YORK

Dr. Hutchings Retires.—Dr. Richard H. Hutchings, superintendent of Utica State Hospital for twenty years, has retired from the state service, having reached the age limit. Dr. Hutchings graduated from Bellevue Hospital Medical College in 1891. He was at one time superintendent of the St. Lawrence State Hospital, Ogdensburg, and formerly professor of clinical psychiatry at Syracuse University College of Medicine, Syracuse. In 1938 he was president of the American Psychiatric Association.

Society News.—At a meeting of the Medical Society of the County of Albany June 28 the speakers were Drs. James A. Hogan on "Lymphogranuloma Venereum"; Harold P. McGan, "Allergic Conditions That Are Frequently Overlooked," and William P. Howard, "Sciatic Pain: Its Relation to Displacement of Intervertebral Disks." — Dr. Frederick W. Williams, New York, addressed the Medical Society of the County of Monroe, Rochester, in May on "Modern Concepts of Diabetic Lesions of the Lower Extremities."

New York City

Hebrew Medical Texts.—The Jewish Theological Seminary of America, Broadway and One Hundred and Twenty-Second Street, invites physicians to visit a summer exhibition of rare old medical texts in Hebrew. The books and manuscripts are from the pens of such writers as Isaac Israeli, Maimonides, Pope John XXI, Nathan ben Joel Falaguera, Moses Narboni and Abraham Kaslari. The exhibition is in the museum of the seminary and is open every day from 10 to 5 o'clock except Fridays and Saturdays.

The New Memorial Hospital.—The new \$5,000,000 building of the Memorial Hospital for the Treatment of Cancer and Allied Diseases at York Avenue and Sixty-Eighth Street was dedicated June 14. In the morning the following addresses were presented:

Dr. Burton T. Simpson, director, State Institute for the Study of Malignant Disease, Buffalo, Pioneer Cancer Institutes in America.
Dr. Frank E. Adair, attending surgeon and executive officer of Memorial Hospital, The Position of a Cancer Institute in Relation to the General Medical Profession.

Dr. Lloyd F. Craver, attending physician at the hospital, Graduate Education in Memorial Hospital.

Dr. James Ewing, director of the hospital, The Planning of the Memorial Hospital Building.

William D. Coolidge, Ph.D., director, research laboratories, General Electric Company, Schenectady, Contributions of the Physical Sciences to Cancer Therapy.

The formal opening and dedication took place at 3 o'clock in the afternoon with the following speakers: Hon. Jacob Gould Schurman, Ph.D., former president of Cornell University; Dr. Ludvig Hektoen, director, National Cancer Council, Washington, D. C.; Dr. Sigismund S. Goldwater, commissioner of hospitals, and Mr. Harry Pelham Robbins, president

Paul Parker Photo

The New Memorial Hospital.

of the hospital. The new building, with 169 beds and twelve stories high, is said to be the largest institution of its kind in the world. Funds for its construction were provided by a grant of \$3,000,000 from the General Education Board and one of \$500,000 from Edward S. Harkness. The site was donated by John D. Rockefeller Jr. Ground was broken June 8, 1937, and the cornerstone was laid May 20, 1938. The new hospital adjoins the Rockefeller Institute for Medical Research, Cornell University Medical College and the New York Hospital. It is equipped with new types of x-ray tubes, one of a million volts and others of 250,000 volts each. Sixty patients in the old hospital were to be removed June 15, and the hospital's supply of radium, 8.5 Gm., valued at \$212,500, was moved later in the week to the lead-lined vault in the new building.

NORTH CAROLINA

Clinic for Venereal Disease.—Six Smithfield physicians have established a weekly clinic for persons with venereal disease who are unable to pay for private treatment but are ineligible for relief. The physicians will take turns at the clinic and will be assisted by a public health nurse. Those participating are Drs. John H. Fitzgerald, George A. McLemore, Abraham H. Rose, Thaddeus G. Upchurch, Charles Watson Wharton and William G. Wilson Jr.

Society News.—Dr. John W. Kinley, Asheville, addressed the Buncombe County Medical Society, Asheville, June 5 on "The Care of Your Patient's Central Nervous System."—Dr. James H. McNeill, North Wilkesboro, addressed the For-

syth County Medical Society, Winston-Salem, May 23 on "The Electrocardiogram as an Aid in Diagnosis."—At a meeting of the Catawba Valley Medical Society May 23 in Hickory, the speakers were Drs. Abel L. Hill, Kings Mountain, on "Dermatophytosis"; Glenn R. Frye, Hickory, "Surgery and the Neurotic Patient," and Silas Raymond Thompson, Charlotte, "Mortality in Prostatic Surgery."

Public Health Association Meeting.—Dr. John W. Williams, Asheville, was chosen president-elect of the North Carolina Public Health Association at its annual meeting in Greensboro in May and Dr. Avon H. Elliot, Wilmington, became president. Dr. William P. Richardson, Chapel Hill was elected vice president and Dr. John W. Roy Norton, Chapel Hill, secretary. Speakers at the meeting included Drs. John A. Ferrell of the International Health Division of the Rockefeller Foundation, New York; John F. Kendrick, Raleigh; Thomas W. M. Long, Roanoke Rapids, secretary of the Medical Society of the State of North Carolina; Louis L. Williams Jr. and Mark V. Ziegler of the U. S. Public Health Service. Henry F. Vaughan, Dr.P.H., health commissioner of Detroit, was the speaker at a banquet.

OHIO

Medical Librarian Retires.—Mr. John Charles Harding, librarian of the Cleveland Medical Library Association since 1906, has retired because of ill health. Mr. Harding first became associated with the library in 1898, when Mrs. Harding was librarian. He served as assistant librarian, keeping the library open in the evenings. In 1906 he became librarian and took part in selecting and building up a collection of more than 53,000 volumes. Mr. Harding was active in the Medical Library Association and was editor of its bulletin for many years. He will go to San Diego, Calif., to live.

Changes in Health Officers.—Dr. Chester S. Heimlich, Attica, has been appointed health officer of Seneca County. —Dr. Lloyd E. Overhulse, Holgate, has been appointed health commissioner of Henry County to succeed Dr. Julius R. Bolles, Napoleon. —Dr. Irvin B. Kievit, Medina, recently resigned as health commissioner of Medina County. —Dr. Geraldine M. H. Crocker, Granville, has been appointed health commissioner of Licking County. —Dr. James I. Nisbet, Eaton, has resigned as health commissioner of Preble County and has been succeeded by Dr. Carle W. Beane, West Manchester. —Dr. Harry Wain, formerly of Chicago, has been appointed health officer of Sidney and Shelby County.

PENNSYLVANIA

Society News.—Dr. Andrew P. D'Zmura, Pittsburgh, addressed the Westmoreland County Medical Society at a meeting at the Mountain View Hotel near Greensburg June 20 on "The Care of Patients Having Early Stages of Heart Failure."—Dr. Leslie N. Gay, Baltimore, addressed the Cambria County Medical Society, Johnstown, June 8 on allergy. —Dr. William James Gardner, Cleveland, addressed the Washington County Medical Society, Washington, June 14 on "The Late Results of Craniocerebral Trauma."—Dr. Frank W. Burge, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, June 9 on "The Pennsylvania Plan for Tuberculosis Control and New Trends in the Treatment of Pulmonary Tuberculosis."

Philadelphia

Promotions at Temple University.—Dr. Reuben Friedman has been promoted to be assistant professor of dermatology and syphilology at Temple University School of Medicine; Dr. Michael Scott, assistant professor of neurosurgery, and Dr. Glen G. Gibson, assistant professor of ophthalmology. Dr. Henry J. Off has been made emeritus professor of otology.

Personal.—An oil portrait of Dr. William H. Teller was presented to the Jewish Hospital June 12 by the staff. Dr. Teller, now surgeon emeritus, served fifty years on the staff. —Dr. Douglas P. Murphy will deliver a paper at the seventh International Congress on Genetics in Edinburgh, Scotland, August 23-30 on "Reproductive Characteristics of the Parents of Congenitally Malformed Children."—Jesse F. McClendon, Ph.D., professor of physiologic chemistry, University of Minnesota Medical School, Minneapolis, has been appointed research professor of physiology at Hahnemann Medical College.

RHODE ISLAND
State Medical Election.—Dr. Charles H. Holt, Pawtucket, was elected president of the Rhode Island Medical Society at the annual meeting in Providence June 7-8. Drs. Lucius C. Kingman and Frederic V. Hussey, Providence, were elected vice presidents and Dr. Guy W. Wells, Providence, is secretary.

SOUTH CAROLINA
Faculty Changes at Medical College.—At the annual commencement of the Medical College of the State of South Carolina, Charleston, June 1, it was announced that Dr. Archibald J. Buist had resigned as professor of obstetrics and gynecology and had been made professor emeritus. In addition the following promotions were announced:
Dr. Bernard S. Kalayjian, to be assistant professor of radiology and electrotherapy.
Chester A. Swinyard, Ph.D., assistant professor of anatomy.
Dr. Mylner W. Beach, professor of pediatrics.
Dr. William H. Kelley, professor of medicine.
Dr. Frederick E. Kredel, professor of surgery.
Dr. Robert B. Taft, professor of radiology and electrotherapy.
Dr. Frank A. Hoshall, professor of orthopedics.

Society News.—Dr. Everett E. Herlong, Rock Hill, was elected president of the South Carolina Urological Association at its recent annual meeting in Columbia.—Dr. Walter E. est, Huntington, W. Va., addressed the Columbia Medical Society June 12 on the Wagner bill and Dr. William Weston, Columbia, discussed anterior poliomyelitis. The society held its monthly meeting July 10 at the Veterans' Administration Facility with a clinical program presented by the hospital staff.—Dr. Louis Schwartz, U. S. Public Health Service, Bethesda, Md., addressed the Greenville County Medical Society, Greenville, May 1 on diseases of the skin caused by exposure to dyes. At the June meeting Dr. Robert M. Dacus Jr., among others, spoke on "Anemias of Pregnancy."—Dr. Gerald E. McDaniel, epidemiologist of the state board of health, Columbia, addressed the Anderson County Medical Society, Anderson, June 14 on "Epidemiology, Symptoms and Early Treatment of Acute Anterior Poliomyelitis."

TENNESSEE
Personal.—Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, received the honorary degree of master of science from Yale University, New Haven, Conn., at the annual commencement June 21.—Dr. Harry A. Saubert, Sevierville, has been appointed health officer of the Upper Cumberland district to succeed Dr. Fray O. Pearson, Livingston, who went to Hamilton County as health officer.

New Board to Supervise State Institutions.—Governor Cooper appointed a new board of physicians June 14 to make a thorough study of the state's institutions and recommend improvements in the present system of medical care for the inmates, it is reported. Members of the board, which is to be known as the "Advisory Board of Medical Care of State's Wards," are: Drs. Hugh J. Morgan, professor of medicine, Vanderbilt University School of Medicine, Nashville; William O. Baird, Henderson, president of the Tennessee State Medical Association, and Joseph H. Francis, associate professor of surgery, University of Tennessee College of Medicine, Memphis.

TEXAS
Personal.—Dr. Minnie L. Maffett, Dallas, was elected president of the National Federation of Business and Professional Women at the annual convention in Kansas City July 14. Dr. Maffett is associate professor of gynecology at Baylor University School of Medicine and physician for women at Northern Methodist University.—Dr. Robert N. Graham, Del Rio, has been appointed health officer of Val Verde County.—Dr. Joe W. May, Donna, was elected health officer of Hidalgo County to succeed the late Dr. Drew R. Handley, Edinburg.

VIRGINIA
Society News.—Dr. John W. Devine Jr., Lynchburg, addressed the Lynchburg Academy of Medicine June 5 on peripheral vascular disease.—At a meeting of the Neuro-psychiatric Society of Virginia at Virginia Beach June 14 Dr. Lawrence F. Woolley, Towson, Md., was the guest speaker on "Psychoanalytic Theory and Practice."
University Appointments.—Dr. Samuel A. Vest, associate in urology at Johns Hopkins University School of Medicine, Baltimore, has been appointed professor and head of the

department of urology at the University of Virginia Department of Medicine, Charlottesville, to succeed the late Dr. John H. Neff. Dr. Edgar Wilson Kirby, formerly instructor in urology, has been named assistant professor of urology and proctology.

GENERAL
New Editor of Nutrition Journal.—George R. Cowgill, Ph.D., associate professor of physiologic chemistry, Yale University, New Haven, Conn., has been elected editor of the *Journal of Nutrition* to succeed John R. Murlin, Sc.D., Rochester, N. Y., who resigned recently. Dr. Cowgill is a member of the Council on Foods of the American Medical Association. The editorial office will be in New Haven.

Report of the Markle Foundation.—The annual report of the John and Mary R. Markle Foundation for 1938 states that the foundation is continuing its policy adopted three years ago of restricting its appropriations to support of medical research. Seventy-two grants were authorized in 1938 and eighty-four projects were in progress during the year. Fields of investigation that were aided include: ophthalmology, mental diseases, deficiency diseases, neurophysiology, disorders of the blood and of the cardiovascular system, fungous diseases, infectious diseases, rheumatoid arthritis and tuberculosis. Appropriations voted during the year amounted to \$573,294. The foundation's principal account had a market value of about \$14,668,000 at the end of the year.

Public Health Program at Obstetric Congress.—The preliminary program of the section on public health of the American Congress on Obstetrics and Gynecology to be held in Cleveland September 11-15 has recently been announced. The general topics for the morning sessions are: public health and maternity care; providing continuity of maternal care in the rural areas; federal and state programs in maternal care in economics and education. The afternoon topics are: the fetus and the newborn, cancer, economics and education, with a summary on the last day. Among the speakers will be:
Dr. Adrian L. Carson Jr., Richmond, Va., A Statewide Program of Prenatal Care.
Dr. Edwin F. Daily, Washington, D. C., U. S. Children's Bureau, Medical Aspects of the Maternal and Child Health Programs.
Dr. Maxwell E. Lapham, New Orleans, Postgraduate Courses in Obstetrics for Physicians.
Dr. Ernest Couture, Ottawa, Canada, The Program for Maternity Care in Canada.
Mr. Perry Addleman, Chicago, Financial Plans for Hospital Care of Obstetric Patients.
Dr. Everett D. Plass, Iowa City, A Proper Division of Obstetric Responsibility.
Dr. Alexander M. Campbell, Grand Rapids, Mich., Maternal Care and Its Economic Aspects.
Dr. William A. O'Brien, Minneapolis, Continuing Education on Maternal and Neonatal Care.
Dr. Leroy A. Wilkes, executive officer, Medical Society of New Jersey, Trenton, will present a general summary of the proceedings of the congress on the last day.

Special Society Elections.—Dr. Daniel L. Lynch, Boston, was chosen president-elect of the American Association of Industrial Physicians and Surgeons at the annual meeting in Cleveland in June, and Dr. McIver Woody, New York, was installed as president. Drs. Lloyd Noland, Fairfield, Ala., and Theodore Lyle Hazlett, Pittsburgh, are the vice presidents and Dr. Volney S. Cheney, Chicago, is secretary. The association has appointed Mr. Armour G. Park, Chicago, who has been the convention manager, as executive secretary.—Maj. Gen. Charles R. Reynolds, U. S. Army, Ret., was elected president of the Association of Military Surgeons of the United States at the recent annual meeting in Washington, D. C. Vice presidents elected were: Col. Harold D. Corbusier, Plainfield, N. J., Med. Res., U. S. Army; Dr. James A. Mattison, Los Angeles, Veterans' Administration; Capt. William L. Mann, M. C., U. S. Navy; Col. Lucius A. Salisbury, Scarsdale, N. Y., M. C., N. Y. N. G., and Dr. Warren F. Draper, U. S. Public Health Service. Maj. Gen. Harry L. Gilchrist, U. S. Army, Ret., is the secretary.—Dr. Fred W. O'Brien, Boston, was chosen president-elect of the American Radium Society at the annual meeting in St. Louis in May, and Dr. Lawrence A. Pomeroy, Cleveland, became president. Dr. William E. Costolow, Los Angeles, is secretary. Next year's meeting will be in New York.—Dr. Elizabeth Mason Hohl, Los Angeles, was chosen president-elect of the American Medical Women's Association at the annual meeting in St. Louis in May.

Report on Eugenic Sterilization.—The Human Betterment Foundation of Pasadena, Calif., reports that the number of eugenic sterilizations performed since the first sterilization

law was adopted in 1907 in Indiana up to January 1 was 30,690. This number does not include sterilization operations performed in states lacking these laws on inmates of state institutions with the consent of the patients. California has sterilized 12,941. The foundation states in its report that its studies, based on California's experience, have shown a marked decrease in sex offenses following sterilization. A study of marriages of 130 feeble-minded patients after sterilization and parole showed that two thirds of them have been successful. "This is as good as the record of all California marriages," the report comments. Only about half the feeble-minded who have been paroled have been sterilized, the report also points out. Of persons admitted to state hospitals for the insane, one in six of new admissions is sterilized. The operations have been divided about equally between men and women; two thirds were insane, one third feeble-minded. The average number during the past two decades has been 546 per year. The Human Betterment Foundation is not designed to take up original scientific work, according to the report, but to investigate the results and possibilities for human betterment by a safe, conservative application of the discoveries made by scientists and to give the information to the public. The officers and trustees will be glad to confer with any one who is interested in the work. The headquarters are at 321 Pacific Southwest Building, Pasadena.

LATIN AMERICA

Personal.—Dr. Ricardo Nunez Portuondo has been elected president of the National Surgical Society of Havana.—Dr. W. H. Hoffmann, Havana, Cuba, a member of the Finlay Institute, has been nominated honorary member of the Robert Koch Institute of Berlin.

FOREIGN

Award for Research on Encephalitis.—The University of Berne, Switzerland, again offers prizes for work on encephalitis lethargica which signifies real progress in the diagnosis or treatment of the disease. The smallest prize amounts to 1,000 Swiss francs. Those who wish to participate should send their applications to the Dean of the Medical Faculty of Berne, which awards the prize at the end of the year.

Deaths in Other Countries

Prof. Archibald Young, regius professor of surgery, University of Glasgow, aged 65, died, July 23.

Government Services

New Naval Medical Center

Ground-breaking ceremonies were held for the new Naval Medical Center on the Rockville Pike at Bethesda, Md., June 29. The \$4,850,000 project includes a new naval hospital, medical school, dental school, quarters for personnel, nurses and hospital corpsmen and subsidiary buildings. When completed, the new center will accommodate the navy facilities now situated in Washington. Rear Admiral Perceval S. Rossiter, formerly surgeon general of the navy, turned the first spadeful of dirt in the ceremonies. Directly across the Rockville Pike from the medical center are the new National Institute of Health and the National Cancer Institute.

Henry Ford Donates Hospital Site

A new Veterans' Administration hospital has been completed at Dearborn, Mich. Erected at a cost of \$1,500,000, the new 351 bed consolidated hospital and regional office is situated on a thirty-eight acre tract of land donated by Mr. and Mrs. Henry Ford. General medical and surgical patients in the Detroit metropolitan area will be cared for. Dr. Clifton H. Smith was transferred from Albuquerque, N. M., to be chief medical officer of the new station. Dr. James A. Howell, previously stationed at Excelsior Springs, Mo., will be in charge of the surgical service, and Dr. Clarence E. Bates, formerly at Wichita, Kan., will be chief of the medical service.

Dr. Frank W. Scott, transferred from Lincoln, Neb., will be the manager and chief medical officer of a new twenty-six bed hospital and regional office at Reno, Nev., which was to be opened May 15. Dr. Scott will be assisted by Dr. Ira J. Seitz, transferred from Cheyenne, Wyo.

A New Method of Keeping Milk

In the scientific journal *Nature*, J. G. Davis of the National Institute for Research in Dairying has described a new and remarkably simple method of keeping milk. It consists in adjusting the pH of fresh milk to 5.2 with diluted hydrochloric acid and maintaining it at a temperature between 36 and 38 F. The milk may thus be kept for a fortnight or more—three or four times as long as commercial cooled pasteurized milk will keep. It may then be brought back to its original pH by adding an equivalent amount of dilute sodium hydroxide and it is said to retain its original flavor. So far the method has been tried on only a small scale, but if it proves equally effective on a large scale it should be useful under many conditions in the milk industry.

Protein in the Treatment of Nephritis

In his Honyman-Gillespie lecture, delivered at the University of Edinburgh, Dr. J. D. S. Cameron combated the treatment of acute nephritis by protein starvation, which has been in vogue since its introduction by van Noorden in 1903. The result is that the tissue proteins are broken down without being replaced, which must produce deterioration in the general state of the body and lower its resistance to infection. The latter is serious in view of the streptococcal cause of nephritis. Moreover, the kidney is not spared the excretion of urea, which is now produced endogenously. Dr. Cameron performed experiments which showed that up to a pint of milk can be taken daily without increasing the amount of urea that the kidney is called on to excrete. He found that on a non-protein diet a subject had an average daily excretion of 6.24 Gm. of urea. The complete metabolism of a pint of milk yields only 6 Gm. of urea.

It has been shown that a high protein diet, such as the meat diet of Eskimos, has no injurious action on the kidneys. Two German physicians, Popischill and Weiss, in 1911 divided scarlet fever patients on admission to the hospital into two groups, one on the customary diet of milk and vegetables, the other on a high protein diet. No difference in the incidence of nephritis was found in the two groups. Encouraged by these observations, workers have been testing the effect of protein feeding in hemorrhagic and acute nephritis. A Scandinavian physician, Naeraa, has recently reported that examination of the urinary sediments in various forms of hemorrhagic nephritis shows nothing to suggest that a high protein diet is injurious to the kidneys. Keutmann and McCann (*J. Clin. Investigation* 11:973 [Sept.] 1932) found that hematuria and albuminuria were not increased in acute nephritis by a high protein diet and that the return of renal function was stimulated.

Though impressed by these results, Cameron hesitated to adopt such revolutionary treatment and compromised, keeping the protein as high as was consistent with the return of kidney function. At the onset he restricted fluid intake to about 2 pints daily. Half of this is provided by fruit juice and dextrose, but 1 pint of milk is given from the beginning of the disease. The nitrogenous excretion was not increased above the endogenous level. As soon as diuresis appears, and with it diminution of the very acute signs—hematuria and blood casts—the caloric value of the diet is increased by the addition of fats and carbohydrates, but additional protein is not yet permitted. With a maximum of from 1.5 to 2 per cent in the

range of urea concentration the diet contains 50 Gm. of protein; of 2.5 per cent, up to 75 Gm.; of 3 per cent, 95 Gm.; of 3.5 per cent, 120 Gm.

Complete recovery frequently takes place in the acute stage. If not the condition passes on to the second stage, characterized by albuminuria, fall in the protein content of the blood and a tendency to edema. Until recently the massive albuminuria has been regarded as an indication for omitting protein from the diet. The result is a further fall in plasma protein, increase of the tendency to edema and lowering the resistance to infection to nothing. When 100 Gm. of protein is given daily the albumin loss is compensated and edema prevented.

Cameron concluded that there is no need to be afraid of protein at any stage of nephritis. Only at the onset of acute nephritis or in the terminal phase of chronic nephritis should protein be reduced to a minimum. It should be provided at all stages as first class protein in order to maintain the general condition. Protein starvation will kill the patient sooner than protein excess.

The Decline of Population

Though the approaching decline of our population has been announced for years by statisticians, this grave prospect has only recently become a burning question. In the House of Lords Lord Samuel said that the number of live births per thousand of women of the child-bearing age in 1891 was 129.8 but that at the census of 1931 it had fallen to 64.3, almost precisely one half. This unprecedented change had taken place not over centuries but in a single generation. There were counterbalancing changes in the death rate, particularly the infantile death rate, and in change from emigration to immigration, but they far from equaled the decline in the birth rate. It was estimated that if the present trend continued the population of England and Wales would by 1970 have fallen from 41 to 30 million and by the end of the century would be only 20 million, and of that number nearly one half would be persons over 60. The means of the decline was contraception, but the cause was economic—poverty or the fear of poverty and the desire to do the best for the children who already had arrived, the desire for enjoyment and to avoid the burden on mothers and the fear of war. As remedies Lord Samuel suggested family allowances and increase of the income tax relief for wives and children.

Lord Dawson said that contraception was extending to all classes and all creeds but that it was not due to a double dose of original sin but to the evolution of life. It was only a specialized example of man's gradual control of nature. The large families of former periods involved a terrible wastage of life, which only rendered the high birth rate possible. Contraception had to grow into our social fabric because of the changed conditions of the people and the reduction of infant mortality. The mothers of today had never been beaten in the training of children. Lord Dawson also recommended family allowances.

For the government Lord Templemore deprecated relying too much on the calculations of eminent statisticians. Some of the forecasts anticipated an earlier decline of population than the facts appeared to justify. For the first time since 1873 the birth rate began to rise in 1934 and this tendency had continued unbroken. This might be the beginning of a reversal of a long continued movement. As to family allowances, in the countries which had adopted them they did not show a significant relation with the changes in the birth rate. In England the change occurred without any artificial stimulus. The pessimistic forecasts were based on a continuance of the fall. It was unlikely that the present population would fall below the present 46 million for two or three decades.

Logan Turner

The death of Dr. A. Logan Turner has removed a prominent laryngologist. The son of Sir William Turner, who was distinguished as an anatomist and educationist, he was born in Edinburgh in 1865. He graduated from the university in 1889 and intended to practice general surgery, but an injury to the hand prevented him from doing this and he took up the special work of diseases of the ear, nose and throat. In the course of a long career he received many distinctions. He was president of the Royal College of Surgeons of Edinburgh in 1925, president of the Sections of Laryngology of the Royal Society of Medicine, honorary member of the American Medical Association, honorary fellow of the American Laryngological, Rhinological and Otological Society and corresponding fellow of the American Laryngological Association. His contributions to medical literature were of the first importance, including "Skiagraphy of the Accessory Nasal Sinuses," "Intracranial Pyogenic Disease" and a biography of his father entitled "Sir William Turner: A Chapter in Medical History." He was editor of a "Manual of Diseases of the Nose, Throat and Ear," which went through several editions, and joint editor from 1921 to 1929 of the *Journal of Laryngology and Otology*.

Treatment of Sterility with Vitamin E

The Department of Chemistry of the University of Witwatersrand, South Africa, in collaboration with gynecologists and the Faculty of Veterinary Science at Onderspoort Laboratory, has been experimenting for eighteen months in the treatment of sterility in human beings and in the lower animals. It now announces that the results obtained from vitamin E, derived from wheat oil, have been so satisfactory that further systematic tests, medical and veterinary, are to be undertaken. An early difficulty was the tendency of vitamin E to decompose, but this was overcome and a sample six months old proved effective.

BERLIN

(From Our Regular Correspondent)

June 29, 1939.

Manganese (Dust) Poisoning

Prof. Ernst W. Baader of Berlin, specialist in industrial diseases, spoke in detail recently before the Medizinische Gesellschaft in Münster, Westphalia, on manganese (dust) poisoning. Manganese is widely used in hardening steel, in ceramics and glass making, in making linoleum, paint and enamel, in the marbling of soap, in chemistry and in the manufacture of dry batteries. Disturbances of health caused by manganese have been accurately described and observed since 1901. Most laborers working with manganese dioxide get sick within the first two years, although cases of manganese poisoning have been observed after from four to five months or even after twenty years of work. The early symptoms are a feeling of heaviness in the legs, uncertainty in turning rapidly and great need of sleep. The fully developed symptoms are a masklike face, periods of uncontrollable weeping or laughter, stuttering, micrography, a characteristic "stilt-walk," stepping on the outer edge of the foot, muscular rigidity and disturbances of equilibrium, so that patients can be thrown over with the lightest touch of the forefinger. The basal ganglions, especially the corpus striatum and pallidum, are regarded as the seat of the disease. Baader takes for granted also a central exophthalmic goiter due to injury of the thalamencephalon. In some cases there is also an initial fever. With better diagnostic methods, many more cases of manganese poisoning may be found; many cases of manganese poisoning are regarded as cases of parkinsonism of unknown etiology. Inhaled manganese dioxide dust may cause pneumonia, as numerous observations indicate.

Purine Metabolism in Gout

Dr. Kühnau, head of the Balneologisches Institut in Wiesbaden, read a paper on purine metabolism in gout and how it is influenced by vitamin B₁ before the Medizinische Gesellschaft in Frankfurt on the Main. The etiology of gout is still incompletely explored. There are two opposing theories. One places the primary disturbance in the kidneys and explains hyperuricemia through impairment of uric acid secretion; representatives of this point of view are Ebstein, Thannhauser and Labbé; the other theory assumes an increased production of uric acid. There are reliable methods to determine nucleotide-N in the blood. Kühnau recently made comparative nucleotide determinations on a large number of persons with normal metabolism and with gout and proved without exception that in real gout the nucleotide level in the blood is increased (from 5 to 10 mg. per hundred cubic centimeters of nucleotide-N as against the normal 2 to 4 mg.) and that nearly in proportion with the uric acid level. Thus in gout, besides uric acid, also its phosphorus containing precursors the nucleotides circulate in increased quantities in the blood. Birch and Mapson observed an increase of nucleotides in the blood also in beriberi; Lecoq was able to produce beriberi in normally fed pigeons through administration of uric acid. It was obvious therefore to assume connections between a decrease in purine and the action of vitamin B₁. In gout the formation of purine bodies is increased to such an extent that the normal vitamin B₁ content of the cells is insufficient to carry through the normal channels the decrease in purine; this can be recognized through increased appearance of inorganic phosphate and uric acid. An increased supply of vitamin B₁ is able to suppress considerably this disturbance. The therapeutic results obtained in gout by the use of vitamin B₁ correspond to this assumption especially in acute attacks; intravenous injections of from 10 to 20 mg. of vitamin B₁ were followed in most cases by sudden disappearance of pains, swelling and redness.

New Causes of Pneumoconiosis

In the course of an expedition to Tanganyika in 1938 two new phases of industrial activity were observed with serious danger of injury to natives through pneumoconiosis. Dr. R. Lehmensick made a report on this subject in the *Medizinische Gesellschaft* in Bonn. In the preparation of sisal the native brushes hemp on brushing machines, forming great clouds of dust consisting of small hemp fibrils and earth dust from the plants; this dust covers the worker like a layer of flour. Although they have been using these brushing machines for only a short while, tuberculosis among the workers has already been observed. It has been estimated that a worker can endure the work for from seven to eight years at most in such shops. The so-called blow-off process in gold mining, such as is practiced in the Lupa region, presents also the danger of pneumoconiosis. In this process earth containing gold is thrown on sifting machines; the earth is blown off next by a strong current of air, which however leaves behind the heavier bits of earth containing gold. Dust created through this process is so thick that one can hardly see. Since the process has been in use for only a short time, disease attacks have not been observed as yet.

Experience in Combating Scoliosis

Prof. Franz Schede, orthopedist, of Leipzig recently made known his experiences in combating scoliosis before the medical society of that city. After he discovered that a developed genuine scoliosis could not be cured with the means available, Schede tried to influence incipient scoliosis in the nursing and the small child. He found that at this stage of development the deformed vertebra could be forced to grow straight again by means of resetting and recumbency, a treatment which lasted from four to six months. In this way he effected a

permanent cure in about thirty cases. In the developed scoliosis of the school child, attention was concentrated on preventing at least a deterioration of the condition. To this end there were necessary (1) the strength of one's own sincere efforts, (2) the regular medical control of all cases of scoliosis with objective methods of measurement, (3) complete easing of all patients with progressive scoliosis for at least a quarter of a year, combined with resetting, recumbency, extension and lying in the open air and (4) the performance of school duties by these children during stationary treatment. To carry out these measures successfully Professor Schede developed an organization which has been functioning satisfactorily for fifteen years. The evaluation of the results has shown puberty to be the most dangerous period for these patients. His observations also confirmed the fact that the prognosis of a case of scoliosis is all the more difficult, the more severe the curvature has become. While patients of grade 1 showed an improvement in 8.6 per cent and neither progress nor regress in 79.7 per cent of the cases to the close of puberty, no improvements at all were noted in grade 3 and only a 14.3 per cent unchanged condition—a further indication of the importance of the early recognition and treatment of this disease.

Progress of Serial X-Ray Examinations

Serial x-ray examinations show considerable progress in Germany. Professor Holfelder of the University of Frankfurt has just reported that the x-ray squads of the SS (protective guards of the party) in Frankfurt, placed under his direction, will take serial roentgenograms of the entire population of Mecklenburg. About 900,000 pictures will be taken; they will be worked up at the roentgen institute of the University of Frankfurt on the Main. Mecklenburg will have thereby, as first national socialist district, a comprehensive "x-ray register" of its population. For this purpose the number of x-ray squads in Frankfurt is to be raised from four to twenty.

Protection Against Aerial Attacks

An institute has recently been organized in Amsterdam for instructing the civil population in methods of protection from attacks from the air. The purpose is to make known all the measures to be taken for the protection of Amsterdam and its population as well as that of other cities. Dr. M. L. Van der Stempel is the director. The instructors will be chosen from among professors, physicians, police inspectors, engineers and chemists. Five courses have been planned for the different classes of pupils. The courses are given every other day to the members of the League of the Nation's Youth. Plans for the erection in Amsterdam of a central school of air protection for the Netherlands have advanced to the point that they can be carried out as soon as the law concerning air protection has been worked out. The following subjects will be treated: 1. History and development of aerial warfare: rights of peoples with reference to it; influence of the League of Nations and the danger of war for the Netherlands and particularly for Amsterdam. 2. Methods of air attack; information on explosives and on incendiary, gas and disease-germ bombs. 3. Chemical warfare. 4. Protection of the individual. 5. Protection of the population. 6. Preparation in times of peace. 7. First aid; care of the sick, wounded and gassed before and after air attacks. 8. Handling of face masks, with practical exercises for the population. 9. Discussion of the division of Amsterdam into sections and quarters and protection of the vital parts of the city. 10. Instruction in first aid in case of accident. 11. Construction and use of oxygen apparatus. 12. Practical exercises in the use of the gas chamber.

Consumption of Raw Milk

In the *Tegen de Tuberculose* review there appeared a study on the use of raw milk in the Netherlands. The growing significance of the tubercle bacillus in cows as causative of tuberculosis in human beings has bred a distrust of raw milk. Therefore the inquiry which Dr. G. D. Hemmes has just ordered made in the province of Utrecht with reference to raw milk consumption is of current interest. Of sixty-five visiting nurses in districts of at least 11,000 inhabitants, fifty-one cooperated in the inquiry. In localities comprising a total of 138,154 inhabitants, 14,015 families were questioned. The source of the milk was likewise indicated. Information was gathered from one tenth of the rural population as to the habitual use of raw milk. Tabulations show that in the province of Utrecht from 10 to 23 per cent of the persons questioned regularly drank raw milk. More than 50 per cent of the consumers drink milk from their own animals.

Combating Favus in the Schools

The question of favus infection and the measures to be taken in the schools have been studied by Drs. H. W. Die-mens and A. J. M. Krens. They point out that the campaign against favus requires instruction not only of the physicians and the population but also of the governing boards of districts (communes) and the school inspectors and commissaries, since these are in a position, according to the law, to seek out and care for pupils infected by favus. It is necessary that they exercise care over the appointment of physicians in all the schools of the Netherlands (these are found at present in only 25 per cent of the schools) and over the organization of a service which will bring to all districts where favus infection is found bandages completely protecting the heads of the children and providing them with a statement attesting that they are regularly treated by a physician. These measures of protection now exist in only 4 per cent of the 1,070 Netherlands districts. To reach children that no longer attend school, it is necessary to prohibit any one from employing them in places where they might infect other persons and to have them watched by the police.

Examination of Rotterdam School Children

M. Feisser, director of the public health department of Rotterdam, has issued an interesting report on health examinations of Rotterdam school children during 1935, 1936 and 1937 with special reference to unemployment. He defines the word "undernourished." One can be undernourished while eating sufficient food. Twelve thousand children attending sixty schools were examined. They were both measured and weighed in 1935 and then divided into groups according to the length of time of unemployment of their fathers (from three to thirty-six months). Little difference was observed between the different groups. The children of unemployed fathers were slightly smaller and lighter in weight than those of employed fathers. In the same way laborers were examined who were previously unemployed but now engaged by the city, and persons previously never unemployed but now holding municipal jobs. The difference in stature is the same as for the children. The unemployed are smaller.

Tuberculosis Research

An institute will shortly be created charged with conducting research in medical hygiene. Research activities on pulmonary tuberculosis will be primarily considered. These have been carried on in increasing measure within the last few years both for collective and for individual profit. The aim of this institute will be to organize and centralize research studies. The erection and maintenance of this institute is made possible by the cooperation of different societies and foundations as well as of placement bureaus and promoting companies. The state will take part in it but only through the department

of instruction, arts and sciences by way of visits of school representatives and through the department of social affairs. An initial capitalization of about 50,000 florins will be credited to the department of social affairs for antituberculosis work. There will probably be no other subsidies.

BUDAPEST

(From Our Regular Correspondent)

June 15, 1939.

The Medical Profession in Hungary

In Budapest the proportion of physicians to the population is 1:370. The total number of physicians is 2,697, of whom 291 are women, 10.6 per cent. The majority of the physicians are between 30 and 35 years of age. As to religion, 1,013 are Roman Catholics, 281 Protestants, 204 Evangelists and 1,137 Jews. According to these figures the percentage of Jewish physicians is 41, while that of the Christians is 59. Of all physicians, 39 per cent are unmarried; 602 physicians (36.7 per cent) have no children, 500 (31.5 per cent) have one child, 344 (21 per cent) have two children, 126 (7.5 per cent) have three children, thirty-seven (2.3 per cent) have four children and twenty-two (1.2 per cent) five children. Four fifths of all physicians practicing in Budapest are specialists and only 20 per cent are general practitioners. Ninety-four per cent of all physicians speak and write German, 33 per cent French, 29 per cent English, 6.6 Italian and 1 per cent Russian. Of all Budapest physicians only 112 own a house, while 2,285 live as tenants and pay rent. Only 57 per cent of all physicians have their own household and 850 of them keep no servants; 25.4 per cent of all doctors get monetary support from their parents or relatives. Permanent occupations are carried on by 10.7 per cent of all consorts. One fifth of all physicians do not own those instruments which are necessary for continuing medical practice. Nine hundred physicians have no telephone, and 17 per cent of all doctors do not subscribe to any journal.

Marriages

JOHN ANDERSON BRABSON, Greenville, Tenn., to Miss Julia Elizabeth McLaurin at Lancaster, S. C., June 24.

WILLIAM MARSHALL BENNETT, Ruffin, S. C., to Miss Evelyn Tallulah Martin of Asheville, N. C., July 6.

ROBERT U. COOPER, Washington, D. C., to Miss Carrye Leonora Johnson in Manchester, Ga., June 1.

DAVID ALEXANDER YOUNG, Raleigh, N. C., to Miss Alma Page Stanley of Belmont, Mass., May 6.

LOUIS GOODWIN SIMON, South Norwalk, Conn., to Miss Elizabeth Abram of New York, July 8.

WILLIAM HEATH BALL, Panama City, Fla., to Miss Mercedes Clarke of Dothan, Ala., May 15.

MARION GRIER FISHER to DR. MARY CHRISTINE GATEWOOD, both of McConnellsville, Ohio, in June.

HUGH M. MOORHEAD to Miss Margaret Krimmel, both of Erie, Pa., in Philadelphia, April 14.

ROYAL W. WALTERS to Miss Elizabeth Stockton Clark, both of Battle Creek, Mich., June 18.

MAURICE J. STONE, Carbondale, Pa., to Miss Dorothy E. Yoffee of Harrisburg, June 25.

SAMUEL F. COHEN, Norristown, Pa., to Miss Roslyn H. Weil of Philadelphia, April 19.

ALLYN BLYTHE CHOATE to Miss Sarah Glover, both of Charlotte, N. C., June 10.

JOHN LESLIE REIGER, Craig, Colo., to Miss Eloise Baldwin of Langer, Wyo., June 26.

WILLIAM HENRY KAUFMAN to Miss Beth Pearse, both of Durham, N. C., May 27.

REESE CLINTON COLEMAN JR. to Miss Louise Kennedy, both of Atlanta, Ga., in June.

Deaths

Dr. William J. Mayo, ♂ former President of the American Medical Association, recognized throughout the world as a brilliant surgeon, a great organizer, an esteemed leader in the field of medicine, died at his home in Rochester, Minn., July 28, aged 78; an operation for perforating ulcer of the stomach had been performed April 22. But a few months have passed since the death of the younger of the two brothers, Dr. Charles H. Mayo. Their careers were inseparable. Their passing from this life so closely together was no doubt as they themselves might have wished it.

The career of Dr. William J. Mayo will be fully recorded in many biographies in which space will be available for proper consideration of its many facets. Since the sixteenth century, the Mayo family has been one closely associated with science. The father of the two boys, Dr. William Worrall Mayo, was born in Manchester, England, May 31, 1819; after training as a physicist and chemist he came to the United States in 1845. In 1847 he removed to Lafayette, Ind., where he studied medicine with Dr. Eleazar Deming. He then completed his medical studies in the University of Missouri and graduated in 1854. After practicing briefly in Laporte, Ind., Dr. William Worrall Mayo removed to Minnesota, settling eventually in Rochester in 1863, where he was in charge of the draft board during the Civil War. The father of these boys was himself a competent surgeon, one of the first physicians in the West to use the microscope, founder of the Minnesota State Medical Association and its president in 1873. Dr. William Worrall Mayo died in Rochester in 1911. He and Mrs. William Worrall Mayo had three daughters and two sons.

The elder son, William James Mayo, was born in LeSueur, Minn., June 29, 1861. The family removed to Rochester when he was slightly over 1½ years old. The boy attended the public school in Rochester and the high school and thereafter spent one year in a private school for languages and science and two years in Nile's academy. During their youth, both William and Charles accompanied their father on his rounds and had an opportunity to observe both surgical operations and postmortem examinations. For a time, both clerked in the drug store. With their father they learned to use the microscope. In 1880, William J. Mayo went to the University of Michigan, Ann Arbor, and completed a three year course which had just been established to replace the former two year medical course. In his medical education Dr. William J. Mayo had an opportunity to be associated with the anatomist Ford and with Victor C. Vaughan, and his training in surgery was under Donald McLean, then professor of surgery. When he was 22, Dr. William J. Mayo completed his medical studies in the university and received his degree.

In November 1884, one year later, Dr. Will married Miss Hattie M. Damon of Rochester. Through many years the close association of Mrs. Mayo with Dr. William J. Mayo in extending hospitality, in the organization of many aspects of the clinic and in carrying a great share of the responsibility for his success and happiness has been widely recognized.

In 1884, Dr. William J. Mayo spent two months in New York City taking the first course given in the New York Post-Graduate School. In 1885 he took a course in the New York Polyclinic. For many years he and Dr. Charles alternated in spending week-ends in Chicago with Christian Fenger. Frequently they traveled abroad to observe surgery as practiced in every nation in the world.

In 1885, Dr. William J. Mayo read his first paper before the Southern Minnesota Medical Association, and his literary contributions to every phase of medical science and art and practice have been innumerable.

From 1889 until 1905, the Drs. Mayo carried on their work in St. Mary's Hospital in Rochester, an institution which they, with their father, had aided in establishing and one which is now known throughout the world largely because of their work. The records of surgical procedures performed indicate an early tendency toward selection of abdominal surgery by Dr. Will, leaving many of the other fields to Dr. Charles. As Dr. Will himself said, "Charlie soon had me driven to cover by being a better surgeon, and I began to specialize in abdominal work and in operations on the ureters and kidneys." As the repute of their work spread, they soon began to associate with themselves younger men who had shown special predilection for surgical work, the first to be selected being Dr. E. Starr Judd, who had charge of the third operating room in 1905. From that time on, the surgical developments in Rochester were so rapid

that additional wings continued to be added to the hospital, an annex was opened and additional hospitals were built. As it became apparent that internal medicine and diagnosis, with the work of the laboratory, would be of prime importance, these developments were particularly encouraged. Throughout the record of the growth and development of this monumental institution to the proud position which it now occupies signs of the leadership of Dr. William J. Mayo appear again and again. Early in his career Dr. Will conceived the idea of a permanent endowed institution in Rochester to be connected with a university. He elaborated the concept of the Mayo Foundation and he gave freely of himself, of his funds and of his life for its perpetuation.

The honors and recognitions given to him indicate how widely recognized were his achievements for the good of mankind. He was a fellow of the American Surgical Association, of the Royal College of Surgeons and of the College of Physicians of Philadelphia. He received the honorary LL.D. from the universities of Toronto, Maryland, Pennsylvania, McGill, Leeds, Pittsburgh, Carleton, Manchester, Temple and Aberdeen. He received the honorary degree of D.Sc. from Michigan, Colum-

bia, Leeds, Harvard, Marquette and Northwestern universities. He received the honorary M.D. from Trinity College in Dublin and from the University of Havana. He was also a fellow of the Royal College of Surgeons, Ireland, of the Royal Accademia Medica di Roma, of the Royal Society of Medicine of England, of the Royal Australasian College of Surgeons, of the Académie de médecine de France. Other recognitions include the gold medal of the National Institute of Social Sciences; the Distinguished Service Medal of the United States Army; the Henry Jacob Bigelow gold medal of the Boston Surgical Society; Royal Order of the Commander of the Northern Star, conferred by His Majesty the King of Sweden; the Finlay Congressional Distinguished Service Medal, conferred by Cuba; the cross of the Royal Order of Knight Commander of the Crown of Italy and the citation for distinguished service given by the American Legion with a commemorative plaque, which was presented by the President of the United States in person in 1934.

Dr. William J. Mayo became associated early with medical organizations. He served as president of his county and state medical associations. He was chairman of the Section on Surgery and Anatomy of the American Medical Association, 1898-1899, and President of the American Medical Association, 1906-1907. He was also president of the American Surgical Association, of the American College of Surgeons, of the Con-

WILLIAM JAMES MAYO, M.D., 1861-1939

DEATHS

52

gress of American Physicians and Surgeons, and of the Interstate Postgraduate Medical Association of North America.

During the World War he was commissioned Major in the Medical Reserve Corps on April 9, 1917, and Colonel of the Medical Corps of the National Army on June 15, 1918. He served as chief consultant for all surgical services during the period of the war and was stationed in the office of the Surgeon General in Washington. He was commissioned Brigadier-General in the Reserve Corps in 1921 and since then has served at various times as consultant in surgery to the War Department.

His memberships in medical organizations, in military organizations and in civic bodies were far too numerous even for listing. Most of the important foreign medical societies of the world had elected him an honorary member.

His contributions to medical literature, previously mentioned, were well beyond 300 in number, beginning with a report of an operation for ovarian tumor and covering many phases of medical and surgical science, a wide variety of commencement and honorary addresses, a number of descriptive letters of travel and philosophic contributions to the problems of our day.

In 1915, Drs. William J. and Charles H. Mayo donated \$1,500,000 to establish the Mayo Foundation for Medical Education and Research in Rochester in affiliation with the University of Minnesota. In 1919 the brothers formed the Mayo Properties Association to hold all the properties, endowments and funds of the Mayo Clinic to insure the permanence of the institution for public service. Again in 1934 the Mayo Properties Association presented a gift of \$500,000 to the University of Minnesota, making a total of \$2,800,000 that the brothers had given to the Mayo Foundation. In sending this contribution, Dr. William J. Mayo wrote, in part:

"Our father recognized certain definite social obligations. He believed that any man who had better opportunity than others; greater strength of mind, body, or character, owed something to those who had not been so provided; that is, that the important thing in life was not to accomplish for oneself alone, but for each to carry his share of collective responsibility. . . . The fund which we had built up and which had grown far beyond our expectations had come from the sick, and we believed that it ought to return to the sick in the form of advanced medical education, which would develop better-trained physicians, and to research to reduce the amount of sickness. . . . The people's money, of which we have been the moral custodians, is being irrevocably returned to the people from whom it came. . . . The practice of medicine in Rochester is carried on in the same manner as by other members of the regular medical profession throughout the state and nation. All classes of patients, without regard to race or creed, social or financial standing, receive necessary care without discrimination. . . ."

These words reflect the great character, the human kindness, the profound human sympathy that were the part of Dr. William James Mayo. It has been said that opportunity and great occasions make great men. Exception to this rule is present in the lives of Drs. William J. and Charles H. Mayo. They made a small village into one of the most notable medical centers of the world wholly through a genius for surgery and for medical leadership. Throughout their careers they devoted themselves to the advancement of scientific medicine and of the medical profession which they served so nobly and which gloried so greatly in their achievements.

In 1906, when Dr. William J. Mayo read his presidential address to the American Medical Association, he forecast and considered some of the great problems that concern medical practice today. He attacked abuses of medical care by public service corporations and the abuse of medical charity by those in the science and art of medicine to dominate its functions. To the very end he contended for this point of view. And in a note written just a few days before his death, he urged continued work for the advancement and stabilization of medical science and the traditions of medical practice.

All the world pauses in the midst of its turmoil and stress to give him honor and to pay him in his death the tribute that is so justly his due—a great physician, a superb surgeon, a magnificent leader, a beloved man!

Arthur Thornton Legg * Boston; Harvard University Medical School, Boston, 1900; member of the House of Delegates of the American Medical Association in 1936 and vice chairman of the Section on Orthopedic Surgery, 1934-1936; was appointed assistant professor of orthopedic surgery at his alma mater and was also at the graduate school; member of the American Orthopedic Association, American Academy of Orthopedic Surgeons and the New England Pediatric Society; fellow

of the American College of Surgeons; associate surgeon, Children's Hospital, Boston; consulting orthopedic surgeon, Lowell General and St. Joseph's Hospital, Lowell, Mass., and Chelsea (Mass.) Memorial Hospital; clinical consultant to the Haverhill Clinic for Crippled Children; orthopedic surgeon to the Lakeville State Sanatorium, Middleboro; in 1910 described a disease of the hip (osteochondritis deformans juvenilis), which is sometimes designated as Legg-Perthes' disease; since 1916 a member of the Harvard Infantile Paralysis Commission; aged 65; died, July 8, of heart disease.

John Allen Hornsby, Washington, D. C.; St. Louis Medical College, 1880; superintendent of the Michael Reese Hospital, Chicago, 1907-1914; formerly professor of medicine at the University of Virginia Department of Medicine, Charlottesville; at one time superintendent of the University of Virginia Hospital, Charlottesville; served as coroner of St. Louis County, as surgeon of the White Pass and Yukon Railway, Alaska, and as a special quarantine officer in Nome, Alaska, and as a medical officer of the U. S. Treasury Department at Nome; during the World War was a confidential adviser to Secretary of War Newton D. Baker and was made chief inspector of military hospitals in the United States and chief of the hospital construction division of the army; co-founder and first editor of *Modern Hospital*; aged 77; died, June 4.

Charles Louis Billard * Washington, D. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; formerly instructor in clinical ophthalmology at Georgetown University School of Medicine and George Washington University School of Medicine; member of the staffs of the Episcopal Eye, Ear and Throat Hospital and Children's Hospital, and formerly a staff member of the Providence and Gallinger hospitals; at one time visiting ophthalmologist at St. Elizabeth's Hospital; aged 60; died, May 1, in the Garfield Hospital of cerebral hemorrhage, hypertensive heart disease and arteriosclerosis.

Ebenezer Ross Faulkner * New York; Halifax Medical College, Halifax, N. S., Canada, 1901; L.R.C.P., London, England, and M.R.C.S., England, 1905 and F.R.C.S., England, 1907; member of the American Laryngological Association and the American Laryngological, Rhinological and Otological Society; a member of the faculty of the New York Polyclinic Medical School and Hospital in the department of rhinology from 1922 to 1925; on the staff of the Manhattan Eye, Ear and Throat Hospital; aged 63; died, May 29, of coronary thrombosis.

Myron Ellis Kahn, Chicago; University of Illinois College of Medicine, Chicago, 1915; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; served during the World War; on the staffs of the Michael Reese and Sarah Morris hospitals and the Winfield (Ill.) Sanatorium; aged 47; died, May 25.

Robert L. Felts * Durham, N. C.; University of Maryland College of Medicine, Baltimore, 1898; fellow of the American County Board of Health; formerly secretary of the Durham and the Duke Hospital; on the staffs of the Watts Hospital heart disease; aged 68; died, May 27, of coronary

William R. Clinton * Detroit; Detroit College of Medicine, 1911; assistant professor of clinical medicine at his alma mater; fellow of the American College of Surgeons; on the staff of the Harper Hospital; served during the World War; aged 49; died, May 29, of pulmonary emboli and diabetes mellitus.

William Hutchinson * Pueblo, Colo.; Denver and Gross Animas County Medical Society; superintendent of the Lasrado Fuel and Iron Corporation Dispensary; aged 59; died, May 17, in the Corwin Hospital, of coronary thrombosis.

David A. Jamieson, Arcadia, Mich.; Detroit College of Medicine, 1894; member of the Michigan State Medical Society; president of the Manistee County Medical Society; for many years member of the school board; aged 73; died, May 12, of acute dilatation of the heart.

John Henry Cumming, Superior, Wis.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; member of the State Medical Society of Wisconsin; aged 67; died, May 1, in St. Mary's Hospital, of pneumococcal meningitis following otitis media.

Edward Bremner Chandler, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1921; since 1928 demonstrator in surgery at his alma mater; on the staff of the Montreal General Hospital; aged 42; died May 12, of rheumatic heart disease.

Henry S. Brookes ☉ St. Louis; St. Louis Medical College, 1884; clinical lecturer on medicine from 1900 to 1906 and clinical professor of medicine from 1906 to 1911 at the Washington University School of Medicine; aged 80; died, May 16, of coronary thrombosis.

Robert Malcom Heath ☉ Pittsburgh; Illinois Medical College, Chicago, 1910; formerly on the staff of St. Joseph's Hospital; aged 61; died, April 24, of bronchopneumonia following a compound fracture of the left tibia received when struck by a truck.

A. Lovelle Burdick, Janesville, Wis.; Hahnemann Medical College and Hospital, Chicago, 1893; member of the board of trustees of the Milton (Wis.) College; on the staff of the Mercy Hospital; aged 73; died, April 21, of myocarditis and arteriosclerosis.

Lucius Walter Holloman, Marksville, La.; University of Tennessee College of Medicine, Memphis, 1913; member of the Louisiana State Medical Society; director of the Avoyelles parish health unit; aged 49; died suddenly, May 19, of coronary occlusion.

Chauncey E. Ehle, Quincy, Ill.; Northwestern University Medical School, Chicago, 1895; member of the Illinois State Medical Society; superintendent of the Illinois Soldiers' and Sailors' Home and Hospital; died, May 23, in the Blessing Hospital.

Simeon Xavier Cordonnier ☉ Carthage, Mo.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; for many years bank president of Avilla; on the staff of the McCune-Brooks Hospital; aged 66; died, May 16, of heart disease.

Samuel Jacob Gold, Peabody, Mass.; Boston University School of Medicine, 1937; on the staff of the Seaview Hospital, Staten Island, N. Y.; aged 27; died, May 28, in Jersey City, N. J., of injuries received when struck by an automobile.

William Johnson Callaway, Florence, Ala.; Birmingham Medical College, 1903; member of the Medical Association of the State of Alabama; on the staff of the Eliza Coffee Memorial Hospital; aged 60; died, May 20, of chronic myocarditis.

Samuel King Davis ☉ Libertyville, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1888; formerly secretary of the Jefferson County Medical Society; president of the local school board; aged 76; died, May 28, of coronary occlusion.

Clarence Herbert Belknap ☉ Detroit; Detroit College of Medicine, 1916; on the staff of the Grace Hospital; aged 47; died, May 4, in the City of Detroit Receiving Hospital (Redford Branch) of injuries received in an automobile accident.

Henry Scott Ware Hardwicke, New York; Hahnemann Medical College and Hospital of Philadelphia, 1905; served during the World War; aged 56; died, May 11, in the Lenox Hill Hospital of chronic cholelithiasis and pancreatitis.

Ephraim J. Burkhart, Johnstown, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; member of the Medical Society of the State of Pennsylvania; aged 75; died, April 18, of coronary sclerosis.

Samuel A. Boland, Loganville, Ga.; Chattanooga (Tenn.) Medical College, 1896; member of the Medical Association of Georgia; aged 66; died, May 24, in a hospital at Atlanta of cardiorenal vascular disease.

Herbert Custer Jones, Little Rock, Ark.; Kansas City College of Medicine and Surgery, Kansas City, Mo., 1922; aged 48; died, May 18, as the result of hanging himself and a self-inflicted bullet wound.

John Berry, Southern Pines, N. C.; Jefferson Medical College of Philadelphia, 1908; served during the World War; aged 54; died, May 25, of coronary thrombosis, arteriosclerosis and hemorrhagic nephritis.

Jeffrey Neese Elder, Hopewell, Va.; Medical College of Virginia, Richmond, 1913; member of the Medical Society of Virginia; served during the World War; aged 49; died, May 11, in Perry Point, Md.

James Arthur Devine, Monte Carlo, Monaco, France; University of Dublin School of Physic, Trinity College, Dublin, Ireland, 1897; aged 70; died, May 12, of heart disease and cerebral hemorrhage.

Eugene C. Brown, Hawkinsville, Ga.; Atlanta College of Physicians and Surgeons, 1900; member of the Medical Association of Georgia; aged 60; died, May 10, of a self-inflicted bullet wound.

Edward Joseph Callow, Seattle; University of Oregon Medical School, Portland, 1930; member of the Washington State Medical Association; aged 56; died, May 1, of chronic nephritis.

Bertha Lund Glaeser, Cincinnati; Woman's Medical College of Cincinnati, 1889; member of the Ohio State Medical Association; aged 78; died, May 5, in the Good Samaritan Hospital.

Earl Elliott Cress, Boyd, Minn.; Northwestern University Medical School, Chicago, 1910; member of the Minnesota State Medical Association; aged 54; died May 14, of coronary sclerosis.

Paul Cole Ridpath, Spokane, Wash.; Jefferson Medical College of Philadelphia, 1900; served during the World War; aged 63; died, April 19, in St. Luke's Hospital of diabetes mellitus.

Waldo Richardson, Los Angeles; Jefferson Medical College of Philadelphia, 1909; served during the World War; aged 62; died, April 20, in St. Vincent's Hospital of carcinoma of the prostate.

Cicero Maxwell Heavrin, Hawesville, Ky.; Kentucky School of Medicine, Louisville, 1888; member of the Kentucky State Medical Association; aged 78; died, May 27, of angina pectoris.

Benjamin Franklin Brooks, Mount Vernon, Wash.; University of Oregon Medical School, Portland, 1901; county health officer; aged 61; died, May 31, of a self-inflicted bullet wound.

Fred K. Day, Longton, Kan.; University Medical College of Kansas City, Mo., 1897; member of the Kansas Medical Society; aged 72; died, May 16, in St. Mary's Hospital, Winfield.

Gainor Jennings, West Milton, Ohio; Cincinnati College of Medicine and Surgery, 1883; formerly member of the school board and postmaster; aged 78; died, May 15, in Miami, Fla.

Erle Walker Hillsman ☉ Trezevant, Tenn.; Vanderbilt University School of Medicine, Nashville, 1900; chairman of the school board; aged 61; died, May 8, of angina pectoris.

Robert Walter Geddes, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1905; aged 63; died, May 7, in the Royal Victoria Hospital, of angina pectoris.

ACETYLCHOLINE IN PAROXYSMAL TACHYCARDIA

To the Editor:—In Queries and Minor Notes in *THE JOURNAL*, June 10, page 2459, a question is answered regarding the use of acetylcholine in attacks of paroxysmal tachycardia. The answer to the question contains a grievous error in failing to distinguish between the highly unstable acetylcholine and the much more stable choline derivatives, such as mecholyl and doryl. One would suppose from reading the answer that acetylcholine would stop attacks of paroxysmal tachycardia when given in doses of from 20 to 30 mg. subcutaneously and that it would cause flushing, salivation, sweating and possibly more serious effects in this dosage. This is completely erroneous. Acetylcholine given in this dosage subcutaneously causes practically no effects whatever, and there is no valid evidence that it has ever stopped an attack of paroxysmal tachycardia.

Had the question read "please inform me regarding the use of acetyl- β -methylcholine (mecholyl) in paroxysmal tachycardia" the answer would have been substantially correct.

Acetylcholine given subcutaneously is a very weak drug. The more stable derivatives are among the most powerful drugs known, so it is essential that physicians distinguish between them.

MEDICAL HISTORICAL ITEMS SOUGHT

To the Editor:—The Medical Society of South Carolina was organized in December 1789 and holds its sesquicentennial this year.

In looking over the old minutes I find that there are several valuable things that have been lost, and of course we are interested in finding them. Many of the valuable old books disappeared during the occupation of Charleston by federal troops; a few of these were recovered just after the war.

Of interest to us is what is called a "portrait miniature" of Dr. Hermann Boerhaave, the celebrated Dutch physician and teacher, 1668-1738. This was presented to the society in 1815 by Dr. Thomas Lining, the grandson of our renowned Dr. John Lining. Dr. Boerhaave presented this himself to Dr. John Lining.

Another is a portrait of John Hunter, 1728-1793, presented to this society in 1854. If through your columns we might be able to find these portraits and volumes we would greatly appreciate it.

JAMES J. RAVENEL, M.D., Charleston, S. C.

President, Medical Society of South Carolina.

FUNGOUS INFECTIONS TREATED BY IONTOPHORESIS OF COPPER

To the Editor:—Although Drs. Haggard, Greenberg and myself (*THE JOURNAL*, April 1, p. 1229) did not claim to have originated a new method of treatment for fungous infections, two investigators, in addition to those quoted in our article, have called our attention to the fact that they had used this method and had published results while our investigations were still under way. In February 1936 Jersild and Plessner (*Bull. Soc. franç. de dermat. et. syph.* 43:450 [Feb.] 1936) reported their successful treatment of epidermophytosis of the extremities by a method varying only slightly from the method used by us. In addition, Martin, Baker and Conant (*Am. J. Trop. Med.* 16:593 [Sept.] 1936) reported successful treatment of blastomycosis by iontophoresis of copper.

Although both of these publications had escaped our notice at the time we published our article, the fact that these investi-

gators have also used this method successfully in the treatment of fungous diseases is gratifying, and we are happy to acknowledge the priority of their publications.

MAURICE J. STRAUSS, M.D., New Haven, Conn.

"COLOSTRIC ANTIBODIES"

To the Editor:—"The demonstration by Schneider and Szathmary of Budapest of an abrupt rise in specific antibody titer of the blood serum of newborn calves following the first feeding of colostrum is confirmatory evidence in support of current belief as to the mechanism of postpartum transfer of maternal immunity."

This is the opening sentence of an editorial, Colostric Antibodies, appearing in *THE JOURNAL*, June 3, page 2289. From this the clinician might gather the impression that colostrum feeding is an essential factor in the immunity of the human newborn infant.

I would like to refer the reader to an editorial, Human Colostrum, appearing in *THE JOURNAL*, Aug. 25, 1923, on the studies of Kuttner and Ratner, then working in the laboratories of Hans Zinsser. To quote directly from the editorial:

On reflection, it is obvious that early immunity may be conferred on the offspring either through the placenta or with the colostrum milk. The records obtained with some species indicate clearly that the placenta is impermeable to proteins and does not permit the passage of maternal antibodies. Indeed, earlier investigators frequently expressed the belief that antibodies appear in the fetal blood only when the placenta is injured in some way; and they regarded placental transmission of antibodies as a pathologic rather than a physiologic process. Such conclusions, it should be emphasized here, were derived from studies of laboratory animals. In harmony with data already on record, Kuttner and Ratner of Columbia University College of Physicians and Surgeons have found that the human placenta is permeable to diphtheria antitoxin. According to their determinations, the concentration of the latter in cord blood corresponds with considerable accuracy to that in the blood of the mothers, there being no measurable loss of antitoxin in passage through the placenta. Kuttner and Ratner state that human colostrum occasionally contains small amounts of the antitoxin; but the quantity is always less per volume than is found in the blood serum of the mother or in the cord blood. In the cases studied, the antitoxin content of the infants' blood failed to show an increase attributable to colostrum feeding. Furthermore, in contrast to what is clearly the case in calves, clinical studies have failed to reveal to the New York investigators evidence of possible harm to the infant resulting from the omission of colostrum from its earliest diet.

How are such apparent discrepancies between the species studied to be explained? Kuttner and Ratner remind us that well known histologic differences in the placentas of the various animals may suffice to account for the varying results with respect to placental exchange. In the human organ the maternal blood is separated from the fetal by a single layer of cells, whereas in the ruminant the placenta consists of three-cell layers. The differences in permeability seem to be in accord with the unlike physical basis offered by the dissimilarity of structure. In goats and cows, with a placental makeup that is fairly complex, placental transmission of immune substances may not occur, so that the colostrum becomes the main agent for transmitting immunity from mother to offspring. In man it is otherwise. In this connection, reference has been made by Kuttner and Ratner to some of the striking differences in the conditions of the mammary secretion in animals, such as cows, with the placenta impermeable, and the newborn calf dependent mainly on colostrum for the transmission of antibodies; and in man, with the placental structure simpler and more permeable. The cow's udder at the time of parturition, they point out, is filled with approximately 20 pounds (9 Kg.) of colostrum, which is immediately and reflexly ingested by the calf shortly after birth to the extent of about 2 pounds (0.9 Kg.) at the first feeding. In human beings, colostrum does not appear for at least twelve hours after birth, and is secreted in amounts not greater than 5 cc. in the first twenty-four hours after birth, and not exceeding 90 cc. after forty-eight hours. In the face of the great interest recently awakened in the possible functions of colostrum, a problem long before physiologists and pediatricians, it would probably be a step too far backward to conclude that colostrum feeding has no significance whatever to the human infant—until the evidence is more compelling. But the earlier enthusiasm for the immunity functions of the first formed milk are being somewhat dispelled so far as the human species is concerned.

I believe that this recent editorial might arouse unjustifiable enthusiasm in relation to the immunity functions of colostrum as far as the human subject is concerned, particularly in the light of Alexis Carrel's leading article in the *Reader's Digest* (June 1939) on breast feeding, in which he states that colostrum is essential for the immunity of the human newborn infant.

This recent work from Budapest is corroborative of the classic experiments of Theobald Smith and his co-workers with the bovine species but is not directly applicable to the human problem. Thus nothing new is added to the situation as it stood sixteen years ago. BRET RATNER, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

THROMBOPENIC PURPURA

To the Editor:—In the light of our present knowledge is the best method of treatment for thrombopenic purpura medical or surgical? Also what is the present status of snake venom treatment in this condition?

M.D., Illinois.

ANSWER.—There is at present no specific medical treatment for thrombopenic purpura. Good results have been reported for many different types of therapy, which in most instances have not been confirmed by further investigation. The probable reason for this is that thrombopenic purpura presents a variable clinical picture; it may be either acute or chronic, and either type may be mild or severe. It is well known that a large percentage of patients with their first episode of acute thrombopenic purpura often recover spontaneously and usually do well on symptomatic treatment alone. On the other hand, the acute fulminating type, characterized by marked bleeding, toxemia, fever and leukocytosis, is refractory to all forms of treatment and usually ends fatally. Patients with this form rarely survive splenectomy.

The treatment of the first episode of bleeding and of the mild attacks of chronic purpura should be medical, such as blood transfusions and snake venom. The use of ascorbic acid, liver extract, parathyroid extract and irradiation of the spleen has not yet yielded consistently good results in chronic cases. Splenectomy should be resorted to if bleeding is severe or is not affected by medical treatment and if recurrence of bleeding is frequent. Splenectomy is curative in the majority of the chronic forms of the disease. It must be remembered, however, that it is associated with a mortality rate of from 15 to 20 per cent.

Although mocassin venom is only a palliative remedy, it should be given a trial in most cases. It usually causes a remission in the acute forms of the disease except in the acute fulminating type, in which it may give severe reactions. It is associated with improvement in about 50 per cent of the chronic cases. It can be determined after a few injections whether the snake venom will be effective by noting the reaction to an intracutaneous injection. A reversal from a positive to a negative local reaction is usually associated with cessation of bleeding, although the platelet count is unaffected.

Two good reviews of the indications and results of medical and surgical treatment of the disease have recently appeared in *THE JOURNAL* (Wintrobe, M. M.; Hanrahan, E. M., and Thomas, C. B., Oct. 9, 1937, p. 1170, and Rosenthal, Nathan, Jan. 14, 1939, p. 101).

HERPES OF CORNEA AFTER SPINAL ANESTHESIA

To the Editor:—A young woman had a pelvic operation under spinal anesthesia. A day or so later a herpetic lesion developed on the left cornea. Is there any connection and what treatment is recommended?

M.D., Michigan.

ANSWER.—Ocular lesions after spinal anesthesia occur quite infrequently. Of these, paralysis of the sixth nerve has been reported in more than 200 cases, but other cranial nerves, such as the third, fourth or seventh may be involved rarely. Most of these reports date back many years, and with the more recent refinements of technic they have practically disappeared. Together with paralysis of the cranial nerves, a series of symptoms such as headache, nausea, vomiting and stiff neck appear and are suggestive of a meningeal irritation. A spinal puncture reveals a high cell count but cultures are usually sterile. Herpes zoster of the ophthalmic branch of the fifth nerve might be due to an irritation of the sensory root.

If the lesion described is herpes simplex of the cornea, it has the significance of and is identical with a "fever blister." This corneal herpes may follow any febrile reaction or any operation, and is due to a virus that can be readily transplanted into a rabbit's cornea. Nonspecific foreign protein therapy and gentle curettement of the sloughing epithelium with a mild antiseptic and anesthetic solution is the customary treatment and should be in the hands of a competent ophthalmologist.

TREATMENT OF AMEBIC DYSENTERY

To the Editor:—What is the best opinion on the usefulness of stovarsol in amebic dysentery as to its therapeutic value during the acute stages and its preventive value after acute symptoms have subsided under emetine?

W. F. Tanner, M.D., Charleston, S. C.

ANSWER.—Stovarsol is not the drug of choice in the treatment of amebic dysentery. If one feels that one must use an arsenical preparation, carbarsone may be given, one tablet three times a day for a period of seven days. A week or ten days should elapse before a subsequent course of the drug is advised. During this time one can examine the stools for the presence or absence of either the parasite or its cyst. Carbarsone has less tendency to give the toxic reactions that have been accredited to stovarsol and it is much more parasitocidal. No arsenicals, however, should be used in the presence of an acute phase if there is any possibility of a hepatic involvement. During this time one may give up to as much as from 6 to 8 grains (0.4 to 0.5 Gm.) of emetine hydrochloride as a total accumulative dose but not more, and, if the emetine hydrochloride is to be repeated, at least ten days should elapse after the last dose before it is started again. In addition to this, if there is an acute phase to the disease and there is a possibility of hepatic involvement, one of the iodine preparations, namely iodoxyquinoline sulfonic acid or vioform-Ciba, should be used. Finally, it is to be remembered that, even though the cysts or parasites may have disappeared from the stools, that is no reason for the discontinuance of the therapeutic barrage at this disease and courses of arsenic or iodine preparations should be kept up at frequent intervals for a period of about one or two months. The patient should then report back at intervals of six months to see that he is free from the disease.

GARRÉ'S OSTEOMYELITIS

To the Editor:—Please advise me as to nature, prognosis and treatment of Garré's osteomyelitis in a girl of 18.

M.D., New York.

ANSWER.—Garré's sclerosing osteomyelitis is a localized, proliferative, chronic, nonsuppurative sclerosing osteitis which appears in the roentgenogram as a spindle-shaped thickening of the bone. The medullary cavity is reduced in size and the bone is increased in density. The lower extremity is more often involved than the upper. The lesion is due to an infection with an organism of attenuated virulence in combination with chronic irritation. A history of pneumonia, influenza, typhoid or other infectious disease may precede the onset. Bennett and Hopkins report a case of sclerosing osteomyelitis associated with trichinosis, although they were unable to establish a causal relationship.

Of the thirty cases reported by Henderson, the tibia was involved in sixteen, the femur in ten, the fibula in two, the ulna in one and the second metacarpal bone in seven. Nineteen patients were males and eleven were females. Twenty-two were under 30 years of age. The condition had persisted an average of six years. Trauma was a factor in seven and infectious disease in eight.

The most commonly affected bone is the tibia, usually in its middle segment in relation to the nutrient artery.

The pathologic changes are characterized by a circumscribed increase in the diameter of the bone, by a thickening and eburnation of the cortex and by a distinct narrowing of the medullary cavity, which might be completely obliterated. Sections of the eburnated bone, when placed under the microscope, show the lacunas to be overactive in the production of bone, causing a localized ivory-like formation in the area involved; the blood vessels are choked off and the vascularity of the medulla is reduced by the encroachment on all sides of the enlarged and thickened cortex. The periosteum is thickened.

The chief symptom is pain, which is of a deep, aching character which is worse at night and exaggerated by physical activity. There is local swelling and heat, and often tenderness on deep pressure. Occasionally the onset may be acute with high fever and leukocytosis, as in cases of suppurative osteomyelitis, but more often it is subacute or chronic. In cases of acute onset, suppuration may ensue. The pain is characterized as boring and deep and is worse on exertion and at night. Tenderness is elicited on local pressure. Bony thickening is quite distinct on palpation and is confirmed by x-ray examination.

At the onset there may be considerable swelling of the soft tissues with venous enlargement and local heat. As this subsides the bony enlargement remains. The bone may actually be increased in length.

In a typical case the roentgenogram reveals a spindle-shaped enlargement in the shaft well away from the epiphysis, a distinct

thickening of the cortex with a smooth periosteal covering, and a narrowing of the medullary cavity due to sclerosis and eburnation.

Laboratory tests may reveal leukocytosis, an increased sedimentation rate, a decrease in the number of red blood cells but a negative blood culture. Serologic tests for syphilis are usually negative.

It may be difficult to differentiate Garré's lesion from syphilis, sarcoma, Paget's disease and osteitis fibrosa cystica. According to Cohn the destructive type may show as much destruction as especially when syphilis and Paget's disease can be ruled out.

In doubtful cases an exploratory incision should be made; examination of the frozen pathologic section taken at the time of operation in order to determine the exact pathologic process will prevent unnecessary amputations.

The course of the disease is long. Recurrences, even after operation, are not infrequent. The condition is usually relieved by removing the cortex from a portion of the bone or by trephining, but it is quite likely to recur and in some instances is resistant to all measures of treatment.

Treatment is surgical. Two procedures have been used to advantage, "gutting" of the bone and trephining with multiple drill holes, the latter extending through both cortices. Relief is obtained by the improved circulatory status, the pain probably being caused by the inability of the blood to flow through the dense bone. Some of the patients in Henderson's series failed to obtain relief by the gutting and were relieved by trephining, while the opposite has been true of others. All foci of infection should be eliminated.

DERMATITIS FROM RUBBER GLOVES AND RINGWORM

To the Editor:—For the past two years I have been troubled with a persistent ringworm of the hands which gets well and then reappears. One month ago I had occasion to keep a pair of rubber gloves on for about six hours, removing them only long enough to re-scrub, and two days later I had a severe dermatitis. Patch tests showed it to be the rubber. Powder and soap gave a negative but a patch test of the glove definitely gave a positive reaction. These gloves were a latex glove made by the Cory Rubber Company of Marion, Ohio. I have had occasion to scrub for twenty minutes caused severe reactions again, and having the gloves on for myself with various gloves but so far I haven't read the results. My ringworm vesicles look much like dermatitis venenata vesicles, so that these gloves may have been the seat of my trouble for a year but I could not figure out why the sudden flare-up. I would appreciate your opinion and the incidence of such sensitizations; also some literature on the subject.

Stanley L. Hardy, M.D., Las Vegas, Nev.

ANSWER.—It is possible that the so-called ringworm attacks were really allergic reactions to rubber. In the manufacture of rubber goods many chemicals are used to which the skin is easily sensitized. Cases of dermatitis, sometimes severe, are common among workers in rubber, and it is not surprising that an occasional case of dermatitis is seen which has been caused by such articles of clothing as sweat pads, rubber stockings or girdles. Manufacturers of rubber goods, for their own protection as well as for the comfort of their workers and customers, are constantly trying to find new methods that will eliminate these hazards.

According to Schwartz (Skin Hazards in American Industry, Pub. Health Bull. 215, page 5), light rubber goods such as surgical gloves are usually made by the dipping process. The rubber is prepared, dissolved in naphtha and placed in trays. Into this solution the molds are dipped, a layer of rubber is deposited on them, they are taken out and dried and then dipped again and again until the rubber is thick enough. Then the rubber must be cured by heat or by chemicals such as carbon disulfide or sulfur monochloride. The latter is responsible for much of the dermatitis caused by rubber.

The rubber during the dipping is sometimes deposited by the aid of an electric current, or porcelain forms are coated with a gel which causes the rubber to deposit when the form is dipped. The chief source of irritation arises from the use of sulfur monochloride in the vapor method of curing. This may leave a small amount of hydrochloric acid on the rubber, which is supposed to be neutralized by ammonia; but this part of the process is not always complete. To guard against irritation from this source, all new rubber goods should be thoroughly washed in a solution of soap and ammonia, then rinsed well before being used. (Obermayer, M. E.: Eczema Due to Hypersensitivity to Rubber, *Arch. Dermat. & Syph.* 27:25 [Jan.] 1933. Schwartz, L., and Andrews, G. C.: Investigation of a Method for Preventing Dermatitis from Dress Shields, *J. Invest. Dermat.* 1:219 [March] 1938).

In a personal communication, Dr. Schwartz writes: "The gel method of making rubber gloves requires curing, and if the gloves are acid cured they may be a source of dermatitis. Rubber gloves in order to be the least possible risk of causing dermatitis should be compounded with accelerators and antioxidants which have not been reported to have caused dermatitis and should be heat cured either by the dry method or by hot water. I think that the Wilson Rubber Company of Canton, Ohio, endeavors to make such a glove."

The method of patch testing may be of great help in choosing the best rubber glove, but is not infallible. It is best to place the patches near the area that has been irritated. After rubber gloves have been used, irritation may be lessened by washing the hands in a weak alkaline solution, then anointing them with rose water ointment, wool fat or a combination of these.

INJECTIONS OF THYROXINE INTO MIDDLE EAR

To the Editor:—I should appreciate receiving the treatment of deafness by injections of thyroxine into the middle ear. Just how are these injections made; how much is given and how often?
M.D., Minnesota.

ANSWER.—The thyroxine treatment of otosclerosis was first advocated by Gray in Great Britain and studied most extensively in this country by Dr. Max Goldstein (*Tr. Am. Laryng. Rhin. & Otol. Soc.* 44:118, 1938).

Thyroxine is used in the form of tablets, $\frac{1}{64}$ grain (0.001 Gm.). One tablet is dissolved in four drops of warm sterile distilled water and injected directly into the middle ear cavity so that it may come in contact with the promontory and oval window. Any syringe and bayonet bent needle may be used.

For anesthesia, an aniline-cocaine hydrochloride solution (chemically pure aniline 90 parts, cocaine hydrochloride 10 parts) has been recommended. Five drops is instilled into the ear for five minutes and then the remaining solution carefully wiped out.

The site of injections is at a point halfway between the tip of the handle of the malleus and the posterior rim of the annulus tympanicus. Immediately after injection the patient sits erect and with the head thrown well backward keeps the mouth open for three minutes. This position keeps the fluid from escaping down the eustachian tube and also insures bathing the region of the round window. Following injection, the patient remains quiet for from twenty to thirty minutes and is not too active the rest of the day.

The treatment consists of four consecutive injections made alternately in the right and left ears at intervals of one week. This allows a period of fourteen days in each ear for the absorption of the thyroxine solution.

"PREGNACOL" PREGNANCY TEST

To the Editor:—Have you any data as to the worth of Ernst Bischoff's "pregnacol" test for pregnancy?
Hilton A. Wick, M.D., New Bethlehem, Pa.

To the Editor:—I should like to inquire concerning the accuracy of the Gruskin test for pregnancy.
Herman C. Graves, M.D., Grand Junction, Colo.

ANSWER.—The Gruskin test for pregnancy (pregnacol) is apparently carried out by injecting intradermally "an antigen prepared from the fetal layer only of the human placenta." The diagnosis of pregnancy is said to be positive if pseudopods arise from the wheal at the site of injection and negative if there is an absence of the pseudopods. The test is discussed in papers by Gruskin (*Am. J. Surg.* 31:59 [Jan.] 1936 and *M. World* 56:109 [Feb.] 1938), and by Schwartz (*Am. J. Surg.* [Aug.] 1936). Graflagnino and von Haam (*South M. J.* 31:169, [Feb.] 1938) state that this test is unreliable. There appears to be no evidence to indicate that this test approaches the reliability of the Aschheim-Zondek or the Friedman test.

TUBERCULOSIS AND EXPOSURE TO THE SUN

To the Editor:—Is there any contraindication to the direct exposure of the chest of a tuberculous patient to the rays of the sun? If so, please explain. Is pulmonary hemorrhage more prone to occur after such exposure and, if so, why?
M.D., Virginia.

ANSWER.—Yes, without the advice of an experienced guide. An overdose of the sun's rays to a tuberculous patient is like an overdose of a drug—highly toxic. Sunlight causes a stimulation in mild doses which is beneficial, but when it is acquired as a result of an extensive exposure which causes

a first or second degree sunburn, it is, like any other burn, toxic. This toxicity causes a nonspecific perifocal reaction which may result in hemorrhage.

The exposure should be for only a few minutes a day at first and then gradually increased until tanning develops, which protects against burning.

PREMATURE GRAYING OF HAIR

To the Editor:—Can anything be done for extremely premature graying of the hair of a child? My niece, now 14 years of age, is getting numerous gray hairs and has had some gray hairs since the age of 10. She will apparently be noticeably gray at 18 at the present rate. She is a normal, well developed girl, there being nothing abnormal in her history except an adolescent goiter which is now present and a lifelong history of an extreme type of allergy. When she was an infant, cow's milk (also goat's milk) produced immediate urticarial wheals when brought in contact with the skin. Attempts to feed her either cow's or goat's milk at that time made her violently ill. There was a lesser, though marked, degree of allergy with regard to eggs. Her father, aged 48, began to gray at about 35 and his hair is now almost white. Her paternal grandfather had gray hairs at 18 and was white haired at 50. In writing this I have an idea that it is a rather hopeless proposition but thought possibly some new ideas might have been developed recently with regard to such conditions.

M.D., Texas.

ANSWER.—Exceptional cases of canities have been reported in which the gray hair resumed its normal color after years of grayness. This restoration of color was in some of these cases spontaneous and in other instances followed long continued medication with pilocarpine or acetic acid. As Galewsky (*Handbuch der Haut- und Geschlechtskrankheiten*, Berlin, Julius Springer, 1932, vol. 13, pt. 1, p. 163) suggests, these were probably cases due to some remediable condition and not to an inherited characteristic, as in the case in question. Ordinary canities, as in the case under discussion, cannot be remedied in any way except by dyeing the hair, which is not recommended.

LABYRINTHITIS FROM MUMPS

To the Editor:—A youth aged 18, on April 7, five days after onset of the mumps on the left side only, suffered dizziness and tinnitus on the left side and vomited every time he arose from his bed. He soon lost his hearing completely on the left side. Will you describe from your sources of information the pathology, etiology (toxic, hemorrhagic and the like) and treatment in such cases. I am using infra-red rays and diathermy and potassium iodide internally.

M.D., Indiana.

ANSWER.—Some involvement of the labyrinth during an attack of mumps is not uncommon. Severe disturbances such as noted in this case are rare. The complication is nearly always unilateral and may be due to a toxic action. With complete loss of hearing in the ear affected, deafness is likely to be permanent. Large doses of potassium iodide probably offer the most hope.

TRANSMISSION OF ECHINOCOCCUS

To the Editor:—Is it possible for a man working in a slaughterhouse to contract echinococcosis through the pores of the skin of the hands? My opinion has always been that the condition is usually caused by the ingestion of the ova. Have you any record of a case of this type being contracted through the pores of the skin of the hands?

Roy C. Noble, M.D., Beatrice, Neb.

ANSWER.—It would not seem to be possible for a man to acquire echinococcosis through the pores of the skin while working in a slaughterhouse. No cases have been found. Daughter cysts have been propagated in rabbits by inoculating the latter with active scolices from hydatid cysts. Gross contamination of an open wound with the contents of a hydatid cyst could conceivably lead to secondary echinococcosis. The usual manner of infection in man is the ingestion of ova from infected dogs, coyotes or wolves.

CANCER AMONG PHYSICIANS

To the Editor:—Please inform me as to the comparative malignancy rate between medical men working with x-rays and those who are rarely exposed. Also the comparative statistics between medical men and the general population, as regards malignancy.

M.D., Canada.

ANSWER.—No comprehensive statistics indicating the comparative incidence of cancer among medical men working with x-rays and those not working with this agent have been found. The same applies to the comparison of the incidence of cancer between medical men and the general population. This statement does not relate, of course, to cancer of the skin, which occurs among radiologists who work with x-rays and radium and are not adequately protected from these agents.

"DROP STITCH IN THE BACK"

To the Editor:—Will you kindly enlighten me as to the cause of so-called dropped stitch in the back? What really happens when a person bends over to put a piece of paper in a wastebasket and is taken with severe pain in the back which frequently seems to "cut the wind off" for a few minutes and leaves him with a lame back that bothers him severely for a week or two? The only treatment that I have found to be of value for these so-called dropped stitch cases is bed rest for a day or two and then strapping the back with adhesive plaster. Heat is of value also. Are the salicylates of value, or what better treatment is there?

M.D., Maine.

ANSWER.—"Drop stitch in the back" is a term which has a restricted use. It evidently corresponds to what has been called a "hexenschuss" or the "witch's shot." The probabilities are that when a person bends over to put a piece of paper in the wastebasket and is afflicted with pain severe enough to "cut off his wind" he has torn a ligament, aponeurosis, fascia or muscle. The application of adhesive strapping, rest in bed, local applications of heat and administration of salicylates either by mouth or by rectum are usually helpful. In some cases a belt, brace or plaster cast is advisable. The condition is more apt to occur in rheumatic persons or those who have fibrositis or myositis.

THIAMIN CHLORIDE SYNTHETIC

To the Editor:—Can any untoward effects be anticipated from prolonged intramuscular injections of vitamin B₁ synthetic?

M. L. Raymond, M.D., Homer City, Pa.

ANSWER.—Many clinicians have given daily injections of as much as 100 mg. of the synthetic thiamin chloride over a considerable period without harm. In all probability such a large dose cannot be fully utilized by the organism, much of the vitamin escaping through the kidney before being "stored" in the tissues or used in its metabolism. From 20 to 50 mg. daily appears to be a valuable therapeutic range when large doses must be given. After about two weeks of such administration the daily dose may well be reduced to 10 mg. and continued until the patient has been relieved of all symptoms. It is unlikely that any dose short of that which would be contraindicated on economic grounds alone would be harmful.

ANTIHEMIC VALUE OF LIVER

To the Editor:—What is the relative value (antianemic value—hematogenic value) of calf's liver and lamb's liver?

M.D., New Jersey.

ANSWER.—There is no experimental evidence regarding the antianemic activity of lamb's liver, but one would assume that it is about the same as calf's liver. The response of the patient to lamb's liver should determine this point.

PELVIC PAIN

To the Editor:—In the May 27 issue of *The Journal* a physician from Illinois inquires concerning postoperative pelvic pain. He mentions the fact that the pain is frequently in the back and radiates down the thighs. May I point out that any patient with pain in the back, particularly if there is radiation of pain down the thighs, should receive a thorough orthopedic examination. Sometimes such an examination will relieve one of the necessity of performing a pelvic operation. If the pelvic operation has already been performed and the back pain and radiation of pain persist, the indication still exists for an orthopedic examination. I am sure that most orthopedic surgeons have seen cases in which pelvic operations have been performed on patients whose major trouble was back pain, with or without radiation, in which the back pain persisted following operation and was relieved by the proper orthopedic measure. I can call to mind at the moment one case in which a young girl whose major complaint was a lumbosacral pain had been advised to have a pelvic operation. Examination showed an old fracture of the coccyx, and when the coccyx was removed the pain disappeared. Another girl, 19 years of age, had a pelvic operation performed, and when the pain persisted examination disclosed a Ewing's tumor in the fourth lumbar vertebra. Such cases occur all too often, and I feel that one needs to bear in mind the orthopedic possibilities in all cases in which there is back pain.

Allen S. Lloyd, M.D., Norfolk, Va.

TREATMENT OF TAPEWORM INFESTATION

To the Editor:—The note on the treatment of tapeworm infestation in *The Journal*, May 20, page 2084, mentions only aspidium, the traditional remedy (*Dioscorides*, "Greek Herbal," Oxford, England, University Press, 1934, p. 585). My attention was recently directed to an article (Sandground, J. H.: *New England J. Med.* 218: 298 [Feb. 17] 1938) in which evidence is cited that seems to indicate that carbon tetrachloride in 4 cc. doses is more effective, and I therefore call this article, which seems to me a good one, to your attention.

Book Notices

The Abnormal in Obstetrics. By Sir Comyns Berkeley, M.A., M.C., M.D., Consulting Obstetric and Gynaecological Surgeon to the Middlesex Hospital and the City of London Lying-In Hospital, Victor Bonney, M.S., M.D., B.Sc., Consulting Obstetric and Gynaecological Surgeon to the Middlesex Hospital, and Douglas MacLeod, M.S., M.B., F.R.C.S., Assistant Obstetric Surgeon, St. Mary's Hospital, London. Cloth. Price, \$6. Pp. 525, with 6 illustrations. Baltimore: William Wood & Company, 1938.

The purpose of the book is to "aid those of the higher examination who are concerned with the abnormal in obstetrics."

The purpose of the book is to "aid those ambitious of passing one of the higher examinations of obstetrics" and the practitioner whose major interest is obstetrics. The authors assume that the reader has a textbook available for reference as to procedures and technic. There are few illustrations because the book is for advanced practitioners. Three well known obstetricians wrote the thirty-nine chapters, and one can distinguish differences in style which do not detract from the value of the work.

According to the introduction, "Prepared by a neoplasm,"

According to the introduction, "Pregnancy is a state induced by a neoplasm. . . . Moreover, these effects are not paralleled by any other new growth and form a distinctive group in the category of disease." The authors seem to go as far as De Lee, who holds that pregnancy is pathogenic and therefore pathologic.

The authors have set themselves a herculean task. They have endeavored to encompass in 500 pages the wide field of abnormal obstetric conditions, as well as most of the medical and surgical diseases and those treated by the specialties. This brevity necessitates that many conditions receive scanty mention, and, on the other hand, sweeping statements are made with little or no discussion; thus "It is never necessary to pack the uterus for postpartum hemorrhage." Such a divergence from the accepted practice certainly requires not only discussion but broad statistical support. Again, "Obstetrical practice is a branch of surgery. As such not one of the operations with which it is concerned can properly be performed without a general anesthetic." Such a statement denotes a dangerous lack of awareness of modern advances in surgical anesthesia. It is too bad the British do not know the blessings of local and block anesthesia.

The opening chapter deals with sterility, and the following chapters deal with various other factors which may be considered appropriate treatment.

The opening chapter deals with sterility; hormonal dysfunction and various other factors are briefly presented and appropriate treatments cautiously recommended. The relationship of the vitamins to pregnancy is discussed, and a short chapter follows on the female sex hormones. The presentation of the toxic states dependent on pregnancy is admirable from the standpoint of treatment. When milder states are accompanied by symptoms of true preclampsia, cesarean section is advised. On the other hand, conservative or medical treatment is advocated when the eclamptic state already exists. The subject matter is weakened by the consideration of albuminuria as a separate entity. This makes for looseness of classification and inaccuracy of diagnosis.

The finest chapter in the book is that embodying the well known

The finest chapter in the book is that on puerperal sepsis, embodying the well known work of Colebrook and his asso-

ciates. Proper emphasis is placed on the cause, and it is borne out that droplet infection from the respiratory tract and air-borne infection by polluted dust are potent factors in producing the disease. In prophylaxis, masking is stressed. The technic of the isolation block of the Queen Charlotte Hospital is given in detail. Prontosil and sulfanilamide therapy are evaluated, and specific instructions are given for administration. Transfusion of blood is recommended only for those patients who have definite anemia.

The American classification for cardiac conditions is recommended, but, in the discussion of anesthesia for cardiac patients, chloroform with oxygen is recommended. When operative procedures are indicated and inhalation anesthesia is contraindicated, spinal anesthesia is proposed with procaine infiltration as an alternative. Chloroform anesthesia and spinal anesthesia in obstetrics, a not small majority claim, are dangerous. Cesarean section has been rather freely recommended; it is recommended for extreme varicose veins of the vulva. The statement is made that the extraction of carious teeth is more likely to be followed by termination of the pregnancy if done after the sixth month rather than before it. For appendicitis complicated by labor, a cesarean section is first done and then an appendectomy. Would not a Latzko abdominal delivery be safer? Mental disorders are ably discussed by Sir Hubert Bond.

The venereal diseases are ably presented, though the authors perhaps lay too much stress on douches and the topical application treatment of gonorrhea. Chapter 14 contains an excellent presentation of diseases of the kidneys, ureters and bladder. The statement is made that if the blood pressure has not returned to normal and albumin has not disappeared from the urine within six weeks the patient most certainly has chronic nephritis. Under uterine dystocia, 5 units of pitocin is recommended for a sluggish uterus in lieu of forceps, though the warning is given that if the baby is not born in thirty minutes it will be asphyxiated. For contraction ring with a dead child and an oblique lie the authors recommend cesarean section rather than embryotomy, which they consider dangerous in this situation. One could imagine such a necessity, but section would be rather a reproach to the art of the obstetrician.

As in most modern textbooks, the classification of Caldwell and Moloy is adopted for the consideration of pelvic deformity. In cesarean section the authors prefer the low cervical section over the classic, but no mention is made of any extraperitoneal method. In the discussion of delay in the birth of the head in breech presentation, the value of forceps extraction is not stressed as much as by French and American accoucheurs. In septic abortion the immediate emptying of the uterus by operative means is advocated, although the authors admit that in severe cases the illness continues.

In the treatment of "accidental hemorrhage" they decry the giving of blood transfusions before the uterus is emptied. In the treatment of placenta praevia, immediate transfusion is recommended if the patient is in shock and the hemoglobin content below 30 per cent. A maternal mortality of 18 per cent is mentioned for manual removal of the placenta in cases of placenta praevia. In the treatment of this condition Berkeley's wide knowledge makes him stress the virtue of a "single" method over "composite" methods. Regarding rupture of the membranes, "We have grave doubt concerning the modern idea of rupturing the membranes early to expedite labor." This statement may well be taken to heart by many obstetricians suffering from that obstetric festination which seems to be epidemic in the world. Two chapters are devoted to diseases of the newborn, and special mention must be made of that splendid portion dealing with erythroblastosis foetalis.

The chapter dealing with analgesia and anesthesia is the poorest in the book. Chloroform is still recommended and spinal anesthesia is condoned. Despite the work of Eastman, nitrous oxide and oxygen are said absolutely to have no adverse effect on either mother or child. The authors admit having had no experience with local infiltration anesthesia or any of the newer forms of nerve blocking. Appropriately enough, one and one-half pages is devoted to the discussion of delayed chloroform poisoning.

The authors' attitude toward the diabetic problem is interesting. The induction of premature labor has no place in their treatment, nor does cesarean section meet with their approval.

The immense number of subjects considered renders the small volume difficult to review, but it is evident that the authors speak from a large and thoroughly digested experience. Their points of view and methods of procedure often differ from those of American physicians, and in this regard, as well as in many others, the book is to be recommended to obstetricians on this side of the Atlantic. The next edition should be twice as large, to enable the authors to complement more fully the knowledge of the abnormal in obstetrics laid down in existing British and American textbooks.

Thirty-Sixth Annual Report, 1937-1938, of the Imperial Cancer Research Fund. Under the Direction of the Royal College of Physicians of London and the Royal College of Surgeons of England. Paper. Pp. 39. London, 1938.

In 1936 Dr. Selbie found that colloidal thorium dioxide in small doses produced sarcoma at the site of the injection in a large proportion of rats and mice. This substance remains in the body indefinitely after injection. The Thirty-Fourth Annual Report contained a warning against the practice of leaving radioactive substances in the human body because of the danger of producing malignant growths. Dr. Foulds injected small quantities into the bases of the nipples of female guinea pigs and obtained one carcinoma and three sarcomas. Ten or fifteen years might be expected to elapse before the drug would produce a tumor in man, and, since the substance has not been in common use for so long, it is premature to conclude that it is harmless because no cancer has been traced to its use.

The report discusses the fundamental difference which is supposed to exist between squamous carcinoma and sarcoma on the one hand and glandular carcinoma on the other hand. In the former it is supposed that the exogenous agent plays the preponderant part, while in the latter the constitutional factor is supposed to be dominant. The opinion is expressed that the search for the stimulus which induces the large and dangerous group of glandular cancers in man may extend beyond the limits of known carcinogenic agents.

Some interesting observations are reported on filtrable tumors and viruses. Experiments designed to test whether a conjunction of tar and virus would produce malignant tumors of the connective tissues in rabbits were started simultaneously in the laboratories of the Imperial Cancer Research Fund and at the National Institute for Medical Research. Tar was injected intramuscularly on several occasions, and subsequently Shope fibroma virus was injected intravenously. The virus localized at the site of the tar injection, producing a fibroma, and in each laboratory one rabbit of a small series subsequently had a sarcoma in the same position. Further studies by Dr. Cramer and Dr. Horning are reported. The simultaneous administration of preparations containing the thyrotropic hormone of the anterior lobe of the pituitary body and of estrone prevented both proliferation of mammary epithelium and degranulation of the anterior pituitary cells, changes which are readily produced by estrone alone. These observations were used in further experiments designed to prevent the spontaneous development of mammary cancer in a strain of inbred mice with a high incidence of mammary cancer.

Dr. Ludford has continued his work on the cultivation of normal and malignant cells on slides and in flasks and has attempted to ascertain the extent to which malignant cells resemble or differ from corresponding normal cells. He found that certain compounds have the property of promoting liquefaction but does not believe that this stimulation of liquefaction is due to a specific action on malignant cells.

Interesting observations on the biology of radiation are reported by Crabtree and Cramer. The retina of the rat was found to be a useful subject for study of the biologic effects of radiation. Their experiments gave no evidence of any dependence of biologic effect on the quality of the radiation used and permitted the following conclusions: 1. Metabolic changes can be induced with small doses of radiation and in a very short time. Glycolysis is damaged almost immediately after the radiation is applied. 2. There appear to be two types of glycolysis, one highly sensitive and one much less vulnerable to radiation. 3. When a given dose in roentgens is applied to tissues but the time of irradiation is prolonged, a significantly greater effect is produced, suggesting that the inhibiting effect is not only a function of the dose but to some extent progressive with time.

Manual of Instructions and Suggestions. Part II: Services for Crippled Children. Child Welfare Division. Harry J. Becker, Director. Paper. No pagination. Lincoln, Nebraska: Board of Control Department of Assistance and Child Welfare, 1939.

The administration of child welfare in Nebraska as described in this manual is a fair sample of the sort of combined medical and welfare program that has grown up in many states. It embraces such diverse elements as the state medical society, the Elks and the American Legion, in addition to a half dozen branches of the county, state and federal government. The successful working of such a program seems to be in about inverse relation to the extent to which governmental, bureaucratic authority is exercised. This manual combines federal, state and local laws and regulations with formal and informal arrangements with voluntary societies. Relations on the medical side are described as follows:

Close cooperation has been maintained with the state medical association and county medical societies and with other professional and lay groups interested in and concerned with the problems of the child suffering with a physical handicap. On recommendation of the federal and state medical technical advisory committees the medical staff has been selected only from the membership lists of national boards representing the various medical specialties. Medical policy is based on recommendations from members of the medical profession.

Cronología, diferenciación, matrícula y distribución geográfica de las sociedades de ciencias médicas. Por Enrique Sparr, secretario de la Academia nacional de ciencias. Homenaje al VI^o Congreso nacional de medicina (Córdoba, octubre 16-21, 1938). Paper. Pp. 153. Córdoba (Rep. Argentina): Imprenta de la Universidad Nacional de Córdoba, 1938.

This is a meritorious if perhaps too ambitious attempt at furnishing in an almost untitled field a chronological account of the foundation, classification, membership and geographic distribution of medical and allied societies throughout the world. One misses some historical background in the form of references to such forerunners of modern medical societies as the guilds of the Middle Ages, the colleges of physicians and surgeons chartered in Great Britain and elsewhere since the sixteenth century and, perhaps in a larger degree, the scientific academies which, beginning with the Academia dei Lincei in 1603, sprang up all over Europe during the next three centuries. It would be idle to expect under the circumstances any mention of the pioneer Society of Scientific Physicians (Schweinfurt, 1652), the Paris medical society (1776), the medical societies in Boston (1735, 1780), New York (1749, 1769), Philadelphia (1765), New Hampshire (1784) and South Carolina (1789), the societies in London for the improvement of medical knowledge (1782) and medical and surgical knowledge (1783), the Lyceum Medicum (1785), the Abernethian Society (1795) and that most exclusive Medical Society (1749) gathering around William Hunter. It would be easy to advance criticisms and point out slips, which are almost unavoidable in works calling for so much tedious research and rechecking. The first medical society in the United States was not the one organized in New Jersey. The dates given for the organization of the New Jersey and the Maryland societies as well as of several other societies are wrong. Most puzzling is the deficient information for Latin America. The medical organizations existing in Mexico under various names since 1732 and in Caracas (1827), Pernambuco (1841), Guatemala (1847), Bahía (1848), Montevideo (1850), Lima (1851, 1876) and, strangest of all, Buenos Aires itself (1822, 1874) are all overlooked. The earliest ophthalmologic organization in the world is not the Deutsche Gesellschaft but the International Ophthalmologic Congress (1857), the term congress being preferred to society, also suggested at the time. Incidentally, international societies, worthy of a chapter to themselves, receive but scanty attention and congresses, usually their most important manifestation, none at all. The membership in American medical organizations is actually much larger than given, and ophthalmologic societies number more than thirty-three in the world and definitely more than seven in the United States. In a number of cases the earliest societies are not those given as such but others now incorporated or fused. Indexes are sadly lacking, and a good model might be found in the more elaborate compilations of the Russell Sage Foundation, the League of Nations and the National Academy of Sciences. One might go on picking errors in other parts of the book, but this is not necessary nor would it serve any useful purpose. A

monograph of this nature must be accepted as the author perhaps intended it, as a sort of preliminary sketch to be enlarged, corrected and improved through the further effort of all interested. It is indeed preeminently a joint, not individual, and time consuming task. The medical profession should altogether welcome this panoramic, if incomplete, view of its collective activities and history.

Universal Diet Calculator of Approximate Food Values: Carbohydrate, Protein, Fat and Calories. By G. G. Geddes. Portland, Oregon: The Author, 1939.

This device is intended as a convenience in calculating quantitative diets, particularly the carbohydrate-restricted diet. Values are given for the approximate protein, fat, carbohydrate and calory content of seventy-six foods, including nine fats, thirty-four proteins and thirty-three so-called higher carbohydrate foods. With a few exceptions, foods representative of the average American diet have been selected. Fish is overemphasized at the expense of the usual cuts of beef, pork, lamb and other meats. In some instances values for individual brands of products such as bases for chocolate-flavored beverages, cheese and oleomargarine are given rather than values representing such foods as a class. The values for the average composition of the foods selected appear to have been derived largely from the food tables included in the Compilation of Diets published by the California Dietetic Association (Spanish American Institute Press, Gardena, Calif., 1932) but the source of this material is not acknowledged. Frequently, important information has been omitted. In the case of eggs, bananas, nuts and other foods in which the shell or rind may constitute a considerable portion of the weight as purchased the chart does not indicate whether the values given represent the edible portion or the food as purchased. Further, the chart does not specify that the canned fruits listed among the foods containing 6, 9, 12 and 15 per cent of carbohydrate are packed in water, not in the usual sugar syrup, and that the soybeans which are classified as a vegetable containing 6 per cent of carbohydrate are green shelled beans, not dried beans. Other inaccuracies noted are that avocados, various nuts, peanut butter and olives have been incorrectly classified as foods high in carbohydrate and that the protein content of a number of foods has not been correctly stated. Baked beans and kidney beans, for example, contain approximately 7 per cent of protein, not 2.5 per cent, as indicated on the chart. These are serious errors where carbohydrate-restricted diets are concerned. However, if all serious inaccuracies could be eliminated, the device might serve as a useful tool in the rapid estimation of many quantitative diets.

Sanitization of the Drinking Glass. Part I: Methods and Procedures. By Jack G. Baker, Chief, Bureau of Foods and Drugs, Department of Public Health, San Diego, California. Part II: Practical Control. By Raymond V. Stone, D.V.M., Director, Bureau of Laboratories, Department of Public Health, Los Angeles County, California. Paper. Pp. 60, with 9 illustrations. Los Angeles: National Association of Sanitarians, Inc., 1938.

This booklet starts with the coining of a word, "sanitization," based on the word sanitize, meaning to make sanitary. It deals with the problem of sanitation as affected by trade practices in handling dishes, especially drinking glasses. It deals with means of sanitization, such as hot water, heat, lye and other caustics and chlorine preparations, with the equipment for their use and with such dish-washing equipment as sinks, drainboards, brushing devices, soaps and detergents, and towels. A chapter is devoted to chlorine preparations and another to inspectional procedures. Brief consideration is given to the value of individual paper service utensils with an amusing, though sufficiently pertinent, side light on the danger of allowing customers to have possession of bottles, especially at baseball games, prize fights and other events where crowds congregate. Suggested laws and ordinances are considered. The second part of the booklet deals with practical control measures, with special reference to washing temperatures, handling of clean glassware, different types of disinfecting methods, solutions and equipment. There is an extensive bibliography. The book should be useful to health officers, to industrial physicians, to restaurant, hotel and refreshment stand operators and to the field inspection personnel charged with the responsibility of keeping eating places sanitary.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Services: Municipality's Right to Provide Health Service System for Employees.—By a charter amendment, the city of San Francisco undertook to provide a system of health service for its employees. A health service board was authorized to adopt a plan for providing medical care to the members of the system and to determine and certify to the controller the monthly sum to be deducted from the pay of members. Members of the service were permitted to select their own physicians, "subject to the rules and regulations of the board" and subject to a provision that the services or supplies must be furnished "at uniform rates of compensation to be fixed by the board." The health service board adopted a plan whereunder the sum of \$2.50 was determined as the monthly deduction to be made from the pay of members of the system. The board duly certified to the controller the amount to be deducted and the deductions were made. The controller, however, refused to make the funds available to the board until the legality of the charter amendment was determined. The treasury of the City and County of San Francisco likewise refused to make disbursements of funds for the same reasons. The board thereupon petitioned the Supreme Court of California for a writ of mandate to compel the controller and the treasurer to make available to the board the funds deducted from the pay of employees.

Whether or not the city could lawfully provide for a health service system for its employees, said the Supreme Court, depended on whether such system was a "municipal affair" within the meaning of the constitution of California, which declares a municipality to be supreme in the field of "municipal affairs." Proper medical attention, freely available to municipal employees and their dependents, should, the court pointed out, have a direct and beneficial effect on their health, and therefore on their efficiency. If a pension or retirement system or provision for sick leave payments at the expense of the municipality is within the municipal power, the present plan, entirely self supporting and having a tendency to decrease sickness and lessen the expense of sick leave, must equally be so. The court thought therefore that the service did constitute a "municipal affair."

It was contended by the defendants that the charter set up no standard to determine what constituted "adequate medical care" as that term was used in the provision exempting from the operation of the health service system employees who had otherwise provided for "adequate medical care." In the opinion of the court, however, the term was clear enough. The charter defined the term "medical care" to include the services of physicians, surgeons, nurses, persons licensed to treat human diseases without the use of drugs, hospitalization, medicines and appliances and dental, optical and other medical treatment and services. In view of the great complexity and rapid changes in medical science, the court thought it to be neither desirable nor possible to set forth in a statute any detailed outline of particular services. Details must be left in such circumstances to the expert administrative board or officer chosen to carry out the legislative direction. It was contended, too, that the charter provision was in conflict with the state insurance code in that it authorized what was in effect an insurance business without a certificate of authority from the insurance commissioner and that the subject of insurance was of statewide concern and not a municipal affair. Although insurance, the court pointed out, may be a matter of general concern, the health and efficiency of city employees is a municipal affair and a plan established by charter to safeguard the health, peace of mind and working efficiency of such employees is validly applied to them, although it might be entirely improper if applied to objects beyond the scope of municipal power. Furthermore, the insurance code deals with the private business of insurance and neither expressly nor impliedly purports to regulate governmental activities of municipalities. It is a well settled doctrine that general words in a statute which might have the effect of restricting governmental powers are to be construed as not

applying to the state or subdivisions. These same considerations, the court continued, disposed of the further contention that the charter permitted the board to practice medicine in violation of the state medical practice act.

It was further contended that the charter amendment was unconstitutional in providing for a compulsory deduction in an uncertain amount from the pay of municipal employees. But, replied the court, no one has a vested right in his public employment except in so far as the right is conferred by statute or other valid regulation. Employment is accepted under the terms and conditions fixed by law and one of the terms of the employment in the present case was the provision for the benefits of the health service system at the charge imposed therefor. The deduction had none of the compulsory features of a tax, for no one was compelled to pay anything, unless he voluntarily sought public employment under the terms and conditions which the law imposed. The right conferred on the health service board to exclude those employees receiving salaries of over \$4,500 a year, in the opinion of the court, was based on the reasonable legislative determination that such persons may be able to provide themselves with sufficient medical care. Likewise, the exemption of those who relied on healing by prayer was designed to avoid interference with the free practice of religion. The exemption of those who already had adequate medical care avoided the arbitrary imposition of the facilities of the system on those who already had provided for equal facilities from another source. The city, furthermore, had a right to include in the system the school teachers and others employed by the school district.

It was finally contended that some of the rules and regulations and practices of the board were, or might be, arbitrary or discriminatory with respect to particular persons. The court thought that there was no reason to consider such a contention, for the only issue before the court was whether the charter amendment and the plan adopted thereunder were valid. If, the court pointed out, in the performance of the duties devolved on the board the rights of any individuals are infringed, the regular procedure of the courts is available to test the action.

The Supreme Court, therefore, issued the writ of mandate prayed for, compelling the controller and treasurer of the City and County of San Francisco to make available to the board the funds deducted from the pay of the employees who were members of the health service system.—*Butterworth et al., Health Service Board of City and County of San Francisco v. Boyd, Controller, et al. (Calif.), 82 P. (2d) 434.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Painful Subcutaneous Tubercles.—Stout reviewed the records of 2,081 cases of cutaneous and subcutaneous tumors and cysts in order to determine in what types of neoplasm paroxysmal pain occurs and thus be properly classified as tubercula dolorosa. Among them there were twenty in which the tumors had occasioned paroxysmal pain. Nine of these were glomus tumors and four were solitary leiomyomas. The other seven were multiple cavernous hemangiomas, venous hemangioma, multiple neurofibromas, fibrosarcoma, keloid, dermoid cyst and a fibroma associated with a benign epithelioma type of sebaceous cyst, both of which were accompanied by paroxysmal pain. Forty other cases of severe pain were found, but the pain was not of a paroxysmal character and it was unassociated with infection. Eighteen different tumors represented this second group. There were also 202 cases in which moderate pain or tenderness was listed. An analysis of the tissues composing the various tumors of the group associated with paroxysmal pain shows that in the majority of them there are found one or more of three tissue types: smooth muscle, blood vessels and nerves.

Whooping Cough.—In investigating the reliability of cutaneous tests for determining the susceptibility of a child to whooping cough, Bazemore and Williams found no evidence to indicate whether a subject is susceptible or immune to whooping cough. Results of the tests made after treatment with pertussis vaccine showed no routine correlation and there was no specific variation from the reactions obtained before such treatment. There was nothing to suggest that a state of allergy developed after treatment with Sauer's vaccine.

Value of Tuberculin Patch Test.—Vollmer and Goldberger report their experience on the reliability of their tuberculin test (Vollmer-Lederle), using a stronger tuberculin than that of two years ago. They wished to determine, by a comparative study of 678 children, whether or not the patch test can be safely substituted for the Mantoux test. None of the children who showed a positive reaction to the Mantoux test with 0.1 mg. of old tuberculin failed to react simultaneously to the patch test. There were even more positive reactors to the patch test than to the Mantoux test. Therefore it seems that the Mantoux test can be replaced by the tuberculin patch test, at least as the first test. Higher concentrations of tuberculin must later be applied intracutaneously in order to rule out completely any tuberculous infection. The patch test might be preferable to the Mantoux test as the first diagnostic measure. The disagreeable local, focal and constitutional reactions that occasionally result from the Mantoux test did not follow the patch test. The authors suggest the following routine for tuberculin testing: 1. The tuberculin patch test is applied and read two days after the patches are removed. 2. Negative reactors to the patch test are retested with the Mantoux test with 1 mg. (0.1 cc. of a 1:100 solution) of old tuberculin or second strength solution (0.005 mg.) of purified protein derivative. 3. Since higher concentrations of tuberculin occasionally cause pseudopositive reactions, both tests are repeated if there is any discrepancy. If the discrepancy remains, the Mantoux reaction is regarded as the deciding one.

Prognosis of Glomerular Nephritis.—A follow-up study of 146 children with glomerular nephritis was made by Snoke in the children's clinic of the University of Rochester School of Medicine from 1926 to 1937. He compares his results with those of a similar study of 178 cases observed from 1920 to 1936 at the Stanford Medical School. A higher percentage of children recovered from glomerular nephritis in the author's Rochester series than in the San Francisco series. He states that the percentage of dead and chronically nephritic patients in the Stanford series was much greater than that in the

Rochester series and suggests sampling and a geographic difference in the clinical manifestations of glomerular nephritis as possible explanations for the differences in the prognosis of the two series.

Treatment of Amenorrhea, Menorrhagia and Sterility.

—After using pituitary gonadotropic extracts for seven years, Campbell and Sevringhaus report the results which may be expected in treating women for primary or secondary amenorrhea, menorrhagia, irregularity of menstrual cycles and for relief of sterility. All the syndromes discussed are considered to be the result of underactivity of ovarian hormones, dependent presumably on underactivity of the anterior pituitary in supplying gonadotropic substance. For accurate diagnoses and conduct of treatment the endometrial biopsy, vaginal epithelial samples secured by pipet and pregnandiol determinations in urine are important aids. If these aids fail to show definite response to treatment, even though menstruation occurs at fairly regular intervals, the treatment may well be increased or abandoned. The use of long series of repeated daily doses, extending for from five to fifteen days at the beginning of each menstrual cycle, seems necessary and appears to be safe. Results are not achieved in a single month. Treatment should be individualized. Timing of the therapy is of especial importance. The authors have been convinced that the sharp increase in the secretory action of the follicle occurs at about the onset of menstruation. Therefore they adopted the onset of flow as the optimal time at which to begin using the gonadotropic factor when follicle stimulation was the objective. Since there is increasing certainty that in a fertile twenty-eight day cycle ovulation occurs on about the fourteenth day, they attempted to concentrate the therapy in the first fourteen days. Examples of success, partial success and failure of the syndromes treated are cited.

Irradiation of Pituitary and Ovaries for Menstrual Disorders and Sterility.—Mazer and Baer state that low dosage irradiation of the pituitary and ovaries resulted in the restoration of the menstrual function in 59 per cent of 106 cases of amenorrhea, 89 per cent of eighteen cases of dysfunctional metrorrhagia during the childbearing age and 57 per cent of twenty-six cases of dysfunctional menorrhagia. It had no effect in three cases of hypomenorrhea. The amenorrhea of two patients was presumably aggravated by the treatment. Low dosage irradiation of the pituitary and ovaries of twenty-six women with normal menstrual cycles resulted in temporary amenorrhea of one who, however, had in the past shown a tendency to amenorrhea. Low dosage irradiation of the pituitary and ovaries was highly effective in sterility of women with functional menstrual disorders (fourteen of twenty-nine sterile women conceived) but had little if any effect on those who menstruate normally.

Hemolytic Jaundice and Macrocytic Hemolytic Anemia.

—During the last six years Watson observed thirty-five patients exhibiting evidence of hemolytic anemia or jaundice. There were twenty cases of the microcytic (familial or congenital) type and fifteen of the macrocytic (secondary or acquired) type. In two of the latter group hemolytic anemia persisted in spite of removal of associated pathologic conditions which might have been considered causal; in one of these cases splenectomy later resulted in cure. Of most significance in distinguishing the familial or congenital from the secondary or acquired type is the predominance of microcytes in the former and of macrocytes in the latter. This distinction should depend on measurement of the average diameter of the erythrocytes and not on the simple inspection of the blood smears. Increased fragility was uniformly encountered in the congenital type but was also observed in two of the patients with hepatic disease who had macrocytosis and increased blood destruction. Autohemagglutination was observed in two cases of macrocytic hemolytic anemia but in none of the cases of the familial variety. Jaundice and anemia were not found to increase in parallel fashion. Except for periods of hemolytic "crises" the opposite tendency was observed. Generally the more jaundiced patients were the least anemic; in fact, the most jaundiced patient was the least anemic, whereas the most anemic individual was not jaundiced. This suggests that a sluggish bilirubin excretory function of the liver, instead of being detrimental, may actually be of benefit in tending to prevent anemia. Increase in circulating erythrocytes, which is often observed immediately after splenectomy, may be produced with epinephrine in hemolytic jaundice before splenectomy. After operation the effect was not obtained.

Etiology of Obesity.—Greene discusses the alterations in caloric intake or caloric requirement during gain in body weight in obese patients, the incidence of evidence of ovarian dysfunction, the relationship of change in body weight to the onset of certain diseases of the hypothalamus, thyroid and pituitary, and the ability of obese patients to lose body weight when low caloric diets are followed. Cases of myxedema, pituitary tumor and chronic encephalitis were selected because corpulence in these diseases is usually cited in support of the contention that alteration of the secretions of the thyroid and the pituitary glands or lesions in the hypothalamus are etiologic factors in obesity. Lesions of the hypothalamus may occur in suprasellar tumors and diabetes insipidus; cases of each are included. The records of 350 cases of obesity, of which about a third were observed by the author, are analyzed by him. Sufficient data were available regarding the food intake and activity during the gain in body weight in 154 cases. Gain in weight was associated with pregnancy or pregnancies without a history of increase in food intake or diminished activity in thirty-two instances. Most of these patients gained from 15 to 25 pounds with each pregnancy, maintained the added weight, and thus became obese after from three to six pregnancies. There were thirteen patients who were either always obese or became obese without a history of change in activity or food intake. The

gain in body weight which occurred simultaneously with diminished activity in 104 instances was accounted for in five cases by change in occupation and in ninety-nine by a long illness, disability or convalescence. Of 300 women, sufficient data regarding menstruation were available for 289. The menses of 143 were normal. Forty-eight had passed the menopause, but the obesity began several years prior to the menopause and the menses had been normal during that time. Ovarian dysfunction could be excluded as an etiologic factor in the adiposity in 191 cases. Obesity began before puberty in five cases, but menstruation was normal. Adiposity began after the menopause in fifteen instances and antedated it in two. Menstruation was irregular in thirty-four cases, absent in thirteen, scanty in five, painful in seven and excessive in seven. Although the incidence of obesity in myxedema, pituitary tumor, chronic encephalitis, suprasellar tumor and diabetes insipidus is high, it was present in most cases before the onset of the other malady. Patients with myxedema, pituitary tumor or chronic encephalitis became either more or less obese; that is, as many patients lost weight as gained weight after the onset of myxedema and pituitary tumor, and loss of weight was five times more prevalent than gain in weight after the onset of chronic encephalitis. Low caloric diets were known to have been followed for an adequate time by 146 patients, and all of them lost body weight satisfactorily. The patients who lost weight on low caloric diets included those who had various menstrual disturbances, those who became obese from unknown causes and those who became corpulent with pregnancy, illness, operation, myxedema, pituitary tumor, chronic encephalitis and increased food intake. Adiposity developed in association with thirty-six different diseases or disabilities in the patients known to have lost weight satisfactorily. Inactivity occurred simultaneously with gain in body weight in 67.5 per cent. A history of an increase in food intake was obtained in only 3.2 per cent.

Arrests in Embryologic Development as Factors in Vision: Brief Review of Embryology of Eye with Associated Anomalies of Arrested Development. D. J. Lyle, Cincinnati.—p. 1037.

Grenz Rays in Diseases of Eye.—Over a period of five years Pfeiffer used grenz rays in the treatment of 302 patients with superficial (surface) lesions of the eyeball, cornea, bulbar conjunctiva, episclera and sclera. The most striking response was observed in ulcers and infiltrates of the cornea, and in these instances there was convincing proof of the effectiveness of grenz rays. Thirty-two patients with various types of ulcers of the cornea were treated, and stimulation of healing was apparent in practically all catarrhal and small marginal ulcers in from one to four days. Trachomatous ulcers seemed to respond promptly. Dendritic ulcers were treated but the results were inconclusive. The next most impressive results were obtained in cases of episcleritis and scleritis. Of sixty such patients treated, benefit was observed in forty-eight, or 80 per cent. Six patients were not benefited in the least. Four patients with scleritis were treated, and all showed definite response. A great variety of types of nonulcerative keratitis were treated and constancy of results was not observed. Most of the twenty-nine patients with superficial punctate keratitis treated obtained relief from discomfort, the condition improved in a few and

that of six cleared during the course of treatment. Five patients with superficial punctate keratitis were benefited but complete cure was not obtained. Six patients with phlyctenular keratitis were treated, and healing of the lesions which might be ascribed to the grenz rays was not observed. Six patients with epithelial dystrophy of the cornea were treated, and the vesicular lesions of the epithelium of two disappeared and after two years have not recurred. Two of the patients were perhaps benefited and two did not have full series of treatments. Four patients with herpetic keratitis experienced relief from symptoms. Three patients with disciform keratitis, two with sclerosing keratitis and three with band keratitis were not benefited. Thirteen patients with vascularized keratitis (parenchymatous involvement) were not uniformly benefited. Their distressing symptoms, however, were relieved in part, and in some instances the vessels were reduced in size. It is the author's opinion that grenz rays succeed in the treatment of surface lesions of the eye as well as other forms of irradiation and have the important factor of safety to commend them. It seems probable that grenz rays will replace other forms of radiant energy in their field of usefulness. Many variable factors remain for study, and much experimentation will have to be carried on before the maximal efficacy of grenz rays will be known.

Acute Postoperative Enterocolitis.—The chance observation of the sloughing of intestinal mucous membrane following radical mastectomy in a case of severe diabetes led Penner and Bernheim to inquire into the factors and mechanisms responsible for this phenomenon. They reviewed the post-mortem records of the Mount Sinai Hospital and the literature for similar cases of acute postoperative enterocolitis. Search of the literature revealed but few reports made in sufficient detail to identify clearly the nature of the process dealt with. The postmortem records of the Mount Sinai Hospital for the last ten years disclosed forty cases in which necropsy revealed pseudodiphtheritic ulceronecrotic enteritis, colitis or enterocolitis. The selection of cases did not include those in which the mesenteric vessels were thrombosed or those in which a diffuse vascular disease was present. Intestinal diseases of known cause, such as typhoid and dysentery, were likewise excluded. In reconstructing the pathogenesis of the lesion, the authors find that the earliest change consists in marked distention of the capillaries and venules, first in the submucosa and subsequently in the mucosa. This is followed by marked submucosal edema and occasional focal hemorrhage in the vicinity of the distended vessels (diapedesis). The arterioles frequently appear to be contracted. The next change consists in focal necrosis of the mucosa, especially of the mucosal folds. With advance of the lesion the areas of mucosal necrosis spread and fuse and extend through varying depths of the intestinal wall,

although in most cases not beyond the submucosa. In the advanced stages the necrosis is accompanied by an inflammatory cellular reaction, and hyaline thrombi are seen in many of the smaller vessels. The lesion appeared consequent to operative procedures in the abdomen, as well as after lobectomy, and it appeared in patients who had not undergone any operative procedures but were suffering from extensive burns and gastrointestinal hemorrhage. The one condition present in all the cases was shock. A similar lesion follows experimental production of shock by a variety of methods.

*Observations on Sensitivity to Poison Ivy. F. A. Simon and E. Lotspeich, Louisville, Ky.—p. 143.

Sensitivity to Poison Ivy.—Simon and Lotspeich discuss the origin and development of sensitivity to ivy, the effect of certain local applications on the clinical course of the lesions and the effect of parenteral injections of poison ivy extract on specific skin sensitivity as determined by contact tests made before and after the injections. They observed that sensitivity to poison ivy did not occur in all individuals exposed to strong postulated. This factor seems to vary in different individuals and perhaps in the same individual at different times. Local applications of three common therapeutic agents did not influence objectively the clinical course of the lesions. Cutaneous tests with serial dilutions of poison ivy extract, performed before and after a series of intramuscular injections of the concentrated extract, indicated that cutaneous sensitivity was not appreciably altered by injections of the small quantities used in these experiments.

Leukocyte Counts and Sedimentation Rates of Adolescents.—Osgood and his collaborators determined the total, differential and absolute leukocyte counts and sedimentation rates of healthy persons from 15 to 18 years of age. The data show that there is no significant difference with age or sex within this group. The results for the entire group are summarized in tables and it is seen that the most useful range of normal is not the extreme range but that range which will include about plus or minus three probable errors, or 95 per cent of healthy individuals. In other words, if a result in a person of this age group falls outside the range, there is less than one chance in twenty that it is normal for that person. The sedimentation rates form a skew curve, with the greater number of determinations falling in the lower rates. It is probable that the rate of 15 mm. in forty-five minutes, which includes 80 per cent of the results, represents the strict upper limits of normal and that the higher rates are due to mild chronic infection in the tonsils, teeth or sinuses not detectable in the routine physical examination.

Intramuscular Injection of Vitamin K.—Cheney points out that a single intramuscular injection of vitamin K in chicks with a prolonged blood coagulation time due to a diet deficient in vitamin K (fowl hemophilia) reduced the time to normal within one hour. This effect was paralleled, to an extent, by the intramuscular injection of 1 cc. of the same vitamin K into the right upper arm of a hemophilic patient. The 1 cc. contained approximately 0.5 Gm. of the vitamin. The injection produced moderate tenderness and induration but no systemic reactions. The blood coagulation times were tested before the injection and hourly for three hours thereafter, then at six hours and then daily for four days. No significant change in the time of coagulation took place, although it was only one hour on the second day compared to an initial time of two hours and forty minutes. Therefore the author concludes that vitamin K may be safely injected into man in the same proportion as in chicks but that no rapid reduction in the blood coagulation time occurs in human hemophilia as it does in vitamin K deficiency in fowls. In a subsequent experiment (ten minutes) within the ten days following the injection of 0.7 mg. of vitamin K in sesame oil. As this patient's blood had been examined a number of times over a period of seven and a half years and the coagulation time had never previously been less than one hour, it is hardly likely that the development of a normal coagulation time for the first time was coincidental. No certain indications for its use have yet been established, but it may prove of value in cases of jaundice in which there is a tendency to bleed.

factor on these fat absorption curves and on hepatic function. All the patients studied were relatively refractory to control measures. Four patients showed elevated plasma bilirubin (from 1 to 2.2 mg. per hundred cubic centimeters). Six patients showed decreased excretion of hippuric acid (Quick). The livers of seven patients were enlarged two fingerbreadths or more below the costal margin. The postabsorption values of the total lipids fell within normal limits except in two cases. No correlation was found between the level or duration of elevation of the total blood lipids and the degree of hepatic damage indicated by several hepatic function tests. A study was made of the effect of betaine chloride therapy on the hepatic function, diabetic status and alimentary lipemia in this group of subjects. In all instances hepatic function was improved. A decrease of alimentary lipemia was associated with an improvement in the diabetes, whereas an increase of alimentary lipemia was associated with no significant alteration. A fundamental metabolic difference of some yet undefinable sort appears to exist which may account for the difference in response of these patients to both a "fat tolerance procedure" and betaine therapy for control of their diabetic state.

Ascorbic Acid and Tissue Saturation.—Belser and her co-workers describe a method for estimating the minimal intake of ascorbic acid which will just maintain the tissues in a state of complete saturation. They determined the requirement of seven subjects by this method and found that two required between 70 and 85 mg. of ascorbic acid to maintain tissue saturation, three required between 85 and 100 mg. and two required more than 100 mg. of ascorbic acid daily. On the basis of body weight the range in requirement to maintain complete saturation for these subjects was from about 1 to 1.6 mg. per kilogram daily.

Fatty Replacement Following Renal Atrophy or Destruction.—Fatty replacement of the kidney, a condition heretofore reported as a rare entity, is in the opinion of Hamm and deVeer a frequent accompaniment of a variety of lesions leading to atrophy or destruction of renal tissue. They present

six cases which illustrate mild, moderate and advanced grades of this condition. In five cases stones and infection were present. The remaining case is an instance representative of a large group of cases of senile atrophy with mild or moderate degrees of fatty replacement. In addition an example of tuberculosis of the kidney with extensive destruction of the parenchyma, accompanied by fatty replacement, is cited from the literature. Fatty replacement is not peculiar to the kidney. A similar process occurs in other organs undergoing atrophy. According to their observations, the authors point out that extensive fatty replacement of the kidney is encountered only in obese patients. It would appear that the process is one of hyperplasia of the adipose tissue normally present in the renal sinus and that this hyperplasia is not the cause of renal atrophy or destruction but is a secondary phenomenon which of itself is of little significance. Of the many descriptive terms suggested, "fatty replacement," as in "pyelonephritis with renal atrophy and fatty replacement," seems most fitting.

Laminagraphy in Sinus Disease and Ocular Disorders.—Cone and his associates believe that, if there is to be a proper evaluation of the relationship of sinus disease as a causative factor in any condition in which spontaneous recovery occurs as frequently as it does in retrobulbar neuritis or other ocular disorders, some critical method of demonstrating and following such patients must be used. Sinus disease was an important finding in five recent consecutive cases of ocular involvement. Laminagraphy of the sinuses permitted an evaluation of sinus conditions not possible by other methods and therefore the authors think that it should be used if there is to be a sincere effort in establishing the relationship of sinus disease to retrobulbar neuritis.

Postural Hypotension.—Browne and Horton point out that a physical examination is never complete until the blood pressure has been recorded with the patient in the recumbent as well as in the erect position. Failure to carry out this simple procedure results in many patients going from physician to physician looking for help because of dizzy spells and weakness. Hourly and daily records of blood pressure in such a case tell

a graphic story. They report a case to emphasize the variations in blood pressure. From time to time cases have been reported in most of which the following phenomena have been exhibited: (1) a pronounced drop in systolic and diastolic blood pressure and syncopal attacks on changing from the recumbent to the upright position, (2) no increase in pulse rate with this drop in blood pressure, (3) decreased sweating and an inability to stand hot weather, (4) excretion of more urine at night than during the day, (5) a false appearance of youth, (6) a slightly low basal metabolic rate, (7) signs of slight changes in the nervous system and (8) concentration of blood urea at the upper limit of normal. Postural hypotension is not a disease but is an expression of inadequate control of the arterial system which may be associated with numerous diseases. As to its underlying cause, there are about as many hypotheses propounded as the number of cases reported. The conclusion is that the vasomotor system plays the predominant part in the decrease of blood pressure in the standing position. In the case that the authors report, not all of the characteristics mentioned were found. The marked fall in blood pressure, the syncopal attacks and the slow, unchanging pulse rate were present. Intravenous injection of ephedrine caused acceleration of the pulse. This showed that the normal function of the cardiac accelerator mechanism with a change in the blood pressure had not vanished. Instead of the inability to stand hot weather the patient suffered most during cold seasons. One of his most bothersome symptoms was excessive nocturnal urination. He possessed the false appearance of youth but not the characteristically low basal metabolic rate. A diminished vibratory sensation was the only sign of slight changes in the nervous system. The concentration of blood urea was in the higher limits of normal.

Nutrition and Night Blindness.—According to Manville, night blindness occurs not only in vitamin A deficiency but also in diseases of the eye such as glaucoma, choroiditis, optic neuritis, toxic amblyopia, pigmented retinitis and detachment of the retina. He presents the results obtained by various investigators in the measurement of night blindness and from these figures it is seen that from 20 to 40 per cent of the population are suffering from various degrees of night blindness. Much has been said about night blindness as a cause of accidents and the author mentions another important phase of night blindness in relation to the increasing number of traffic accidents. This has to do with the pedestrian and not the driver. Observations in Portland indicate that a large majority of pedestrians killed by automobiles are 50 years of age or older. It is just as likely or even more probable that an individual in this age group, in contrast to drivers as a group, will be suffering from vitamin A deficiency and consequently night blindness. Certainly cirrhosis of the liver and perhaps other pathologic changes occurring in the liver among the aged is of far greater frequency than among younger people. This would predispose to a vitamin A deficiency.

Carbon Monoxide Poisoning Simulating Ulcer.—Beck points out that Bulletin 582 of the United States Bureau of Labor Statistics lists eighty-one occupations in which workmen are exposed to the danger of carbon monoxide. This list does not include exposure incident to the domestic use of gas and oil or that due to riding in closed motor vehicles, 5 per cent of which have been found to contain dangerous amounts of carbon monoxide because of defective engines and exhausts. The author limits his discussion almost exclusively to the gastrointestinal aspects of chronic carbon monoxide anoxemia with special emphasis on a syndrome closely simulating peptic ulcer. Chronic carbon monoxide anoxemia may be clinically divided into simple anoxemia (without any demonstrable tissue changes) and hematologic, cerebrospinal, cardiovascular, respiratory, urogenital and gastrointestinal anoxemia in which definite morphologic changes occur. In a group of 140 individuals studied clinically with daily exposure to varying amounts of carbon monoxide over considerable periods of time, gastrointestinal symptoms were frequently manifested. Statistics show that nearly twice as many workmen employed in gas plants become ill as those engaged in occupations not involving exposure to carbon monoxide and that the incidence of gastrointestinal diseases is two and a half times greater in the first group than in the second. The chief symptoms were anorexia, nausea, vomiting and abdominal pain. The pain was either localized in the midepigastria area or diffused throughout the entire abdomen. In some instances it was dull and aching in character, in others sharp, cramplike and spasmodic. The latter was frequently associated with cardiospasm or pylorospasm. In several instances it was due to enterospasm or anospasm.

Certain patients without demonstrable lesions gave a history suggestive of peptic ulcer including chronicity, periodicity and rhythmicity of symptoms with food ease, hunger pain, pylorospasm and a tendency to bleed. The condition cannot readily be differentiated from peptic ulcer clinically, as hemorrhage, pylorospasm and filling defects may occur in both. The history of exposure to carbon monoxide and the prompt relief of all symptoms incident to a change to a pure atmospheric environment without specific ulcer treatment should exclude the latter. The subject needs further clinical investigation. Seven cases are reported which direct attention to the problem, which heretofore has not been generally recognized and one which has not been satisfactorily solved. It unquestionably is responsible for frequent errors in diagnosis. The gastrointestinal manifestations of chronic carbon monoxide poisoning should not be regarded as a clinical entity but rather as a syndrome developing from a state of chronic anoxemia. This conception is based on the knowledge of the effect of carbon monoxide in producing, through oxygen deprivation, either functional impairment or actual organic changes in the different organs of the body. The lesions produced, which are chiefly vascular, may cause symptoms simulating other diseases besides peptic ulcer. Thus in the central nervous system symptoms of epilepsy, chorea, encephalitis and multiple sclerosis have been observed, and in the cardiovascular system angina pectoris, coronary thrombosis, infarction and myocardial degeneration have been observed.

Treatment of Sulfanilamide-Resistant Gonorrhea.—Alyea and Daniel used sulfanilyl-sulfanilamide in forty cases of gonorrhea resistant to sulfanilamide; twenty-two were cured promptly; five were improved and in thirteen no improvement occurred. The dosage was approximately 3 Gm. daily for from ten to fourteen days. Experimentally the toxicity of sulfanilyl-sulfanilamide is less than sulfanilamide and the patients tolerated it more easily. Acute hemolytic anemia or granulocytopenia did not occur following treatment with sulfanilyl-sulfanilamide, nor were there any serious toxic manifestations involving the hematopoietic system. Peripheral neuritis was encountered only once and the etiologic factor in this instance was questionable.

Causes of Colonic Cancer.—Barga tries to substantiate some of the features of current hypotheses concerning the nature and pathogenesis of cancer. It is generally accepted that the single cancers of mucous surfaces are in the nature of anarchic cell masses originating from a single cell which began its career by a wholly useless and purposeless division and the new cells resulting from it carried on in the same manner. Such cell masses grow rapidly, destroy the surrounding tissues of the host, spread to distant parts and, by sapping the vitality of the patient, finally destroy him. Such cell masses may originate in different parts of the same organ or even different organs of the same person. These facts would suggest that the normal metabolic processes of growth are in constant conflict with some pernicious cellular degenerative process which tends to

gain the upper hand with advancing years. In the tissues of some families this conflict is probably keener and an inherent susceptibility to a weakness in some tissues may exist. This is well illustrated by members of one family in which cancer appears at the same site and at the same time of life. Among the factors which tend to initiate these unnatural processes of growth, the major roles seem to be held by trauma, irritation and infection. All three of them probably come into play in the production and healing of the lesions of a disease such as chronic ulcerative colitis. It is not inconceivable that here the mechanism of normal healing has lost control and the anarchic processes have the upper hand.

Nicotinic Acid for Pruritus Vulvae.—Dabney used nicotinic acid in the treatment of eight women with pruritus vulvae of unknown etiology. Four of the women were relieved. Two of them also had pruritus ani which was relieved. The pruritus of the four patients who were not relieved was somewhat more severe and its duration was distinctly longer than in the patients who obtained relief. The average duration of the condition in the women who were benefited was fourteen months, whereas the others had suffered for an average of almost six years. Since nicotinic acid, though synthetically made at the present time, is merely a vitamin and a member of the B group, relief from pruritus vulvae through its use should be temporary unless repeated. Hence, after the therapeutic test has determined its need, a well balanced, high calory diet, especially rich in vitamin B, is indicated. Two of the successfully treated patients had subsisted principally on starchy foods and with but little animal protein. The diets of the unsuccessful group varied from fair to good. No patient with pruritus vulvae should receive this treatment until a most careful study has ruled out such etiologic factors as pediculosis pubis, diabetes, the fungoid dermatoses, trichomoniasis, gonorrhea, infestation with *Monilia albicans* and certain allergic states. The author believes that the dose of nicotinic acid, 100 mg. three times a day after meals, that he used was far too large and that it caused several unpleasant though harmless reactions. He is going to use 20 mg. three times a day and this amount will be increased only when deemed necessary.

*Relation of Vitamin D and Mineral Deficiencies to Dental Caries. G. F. Taylor and C. D. M. Day.—p. 919.

Vitamin D, Mineral Deficiencies and Dental Caries.—Taylor and Day determined the vitamin D deficiencies and dental caries in ten cases of severe clinical rickets, with x-ray confirmation. A diet and health survey of the Kangra District of the Punjab recently carried out by the public health department has shown a high incidence of rickets and osteomalacia and definite vitamin D, calcium and phosphorus deficiencies in the diet of most of the population. Fifty children with rickets were examined clinically and dentally. A low incidence of dental caries and hypoplasia was observed. Ten of these children were examined roentgenologically, the teeth of four of these had no caries, and in the six other children a total of fourteen cavities were found. There were in the group ninety-six temporary teeth and 135 permanent teeth. Two cavities were found in the ninety-six temporary teeth and twelve cavities in the permanent teeth. The diet of these children consists mainly of carbohydrates with relatively small proportions of protein and fat. Meat and fruits are almost entirely absent from the diet. Small quantities of milk and vegetables are consumed. Sugar is rarely eaten. Only two meals are eaten daily, of rice and "chapatti." Rickets and osteomalacia are very common in the population. On the basis of the investigation the authors conclude that vitamin D deficiency alone does not cause either dental caries or hypoplasia of the teeth. Both the teeth and the jaws of this group of children were excellently formed. This low incidence of caries with excellent teeth and jaw formation is evidently characteristic of the peasant of the Punjab. In another investigation of 800 school children, made in the city of Lahore, of the Indian "middle class," having a diet more in keeping with European standards, including soft refined carbohydrates and sugar, eaten three or four times daily, the incidence of caries was much higher than in the rickets cases. An average of six cavities per child was tabulated for the 800 children. In another group of twenty-six poor Indian children in an orphanage in Lahore, consuming a diet resembling that of the Kangra children, the incidence of caries was 2.27 cavities per mouth. Eight of the twenty-six children had no caries. The low caries incidence of children in the Kangra District and in the orphanage together with the physical nature of the food eaten lends support to the "detergent diet" theory of Wallace, which postulates that the physical nature and cleansing action of the diet is of more importance than other factors in the prevention of dental caries. Furthermore, sepsis and the exanthems of childhood would seem to be more potent factors in the causation of hypoplasia and caries than vitamin D and mineral deficiencies.

Sulfapyridine in Ape Malaria.—From the experiments on three monkeys (*Silenus rhesus*) Chopra and Das Gupta find that, unlike other sulfanilamide compounds, sulfapyridine is capable of destroying the monkey plasmodium (*Plasmodium knowlesi*) in dosage which is even less than what is regarded as the proportionate dose for a monkey as compared with that of man. Once the parasites disappear, after treatment for five days they do not appear again in the peripheral blood, at least not in sufficient numbers to be detected in thick films. This is different from what happens after treatment of *Plasmodium knowlesi* infection with atabrine. Although atabrine exerts a powerful action on this infection, the parasites almost invariably reappear in from ten to fifteen days and multiply with the same rapidity as in the primary attack, causing the death of the animal if prompt treatment is not instituted. In view of the encouraging results obtained with this drug in monkey malaria, the authors believe that sulfapyridine is well worth trying in human cases of malaria.

Sodium and Chlorine Retention Without Renal Disease.—During the last few years Allott encountered five patients not suffering from renal disease in whom a high level of sodium and chlorine was found in the blood. All the urines showed extremely low sodium and chlorine, with high concentrations of potassium, phosphate, sulfate and urea; all were strongly acid, even in the patient who was suffering from alkalosis. Except in this last case there was no evidence of disturbance of the usual acid-base relationships in the serum. The fairly close agreement between the values for total fixed base and total determined acids shows that there is no accumulation of "undetermined acids" such as occurs in uremia due to chronic nephritis. The kidneys in general showed normal glomeruli, apart from slight focal ischemic fibrosis, but some

showed tubular degeneration. The mechanism by which this condition originates is not clear. All the patients, it is true, showed to some extent the clinical symptoms of dehydration, but in most patients with dehydration this accumulation of sodium and chlorine in the blood is not observed. All the patients, except one whose brain was not examined at post-mortem, had a lesion in the central nervous system. The lesions were varied in nature and distribution and it is difficult to find any factor common to them all. The explanation seems to be that either the tubules handle chloride and sodium in a similar manner to dextrose and reabsorb a certain maximal quantity per unit of time, whatever the level in the blood, or that there is some abnormality in the nervous or endocrine influences acting on the kidneys.

Trendelenburg's Operation for Pulmonary Embolism.

—Lewis describes the first successful pulmonary embolectomy in Britain, being the twelfth in the world literature. Apart from its interest as a Trendelenburg embolectomy, the case presented a series of complications almost any of which might have proved fatal of itself in such a dangerously ill patient. The complications were (1) pronounced cerebral symptoms—prolonged unconsciousness, clonic convulsions, amaurosis, deafness and psychologic changes, (2) a second embolism, (3) suppurative mediastinitis and pericarditis treated by drainage and chemotherapy, (4) hemorrhagic pleural effusion which later became an empyema, (5) massive necrosis of the buttocks and (6) the scalenus anticus syndrome. All these conditions were duly overcome.

*Agglutination of Suspensions of Virus-like Particles Prepared from Exudates in Acute Rheumatic Fever. G. H. Eagles and W. H. Bradley.—p. 173.

Secretin Test of Pancreatic Function.—Lagerlöf points out that an absolute condition for a reliable secretin test is the complete separation of gastric and duodenal secretion. A further condition is the complete recovery of the whole juice secreted. This technical problem has been solved by means of a special double tube and continuous separate delivery of the juices of the stomach and the duodenum as well as the saliva. One bore of the tube ends in the stomach, the other in the duodenum. Each one has several holes in its terminal portion, except for the 3 inches of the duodenal tube which occupies the pyloric region. By this procedure the recovery of the juices is complete and reliable. Immediately after intravenous injection of secretin, an abundant flow of pancreatic juice occurs. The volume of pancreatic juice is directly proportional to the amount of secretin injected. Three different mechanisms cooperate in the stimulation of the pancreas: (1) stimulation by secretin, (2) vagal stimulation and (3) stimulation by the split products of digestion. For the diagnostic test the volume collected in one hour is used. Bicarbonate, diastase, trypsin and lipase are determined. When the course of an acute pancreatitis is followed by repeated secretin tests, the volume of juice and the amounts of bicarbonate may remain normal throughout the disease, while during the acute stage the enzymes are depressed but later, during convalescence, return to normal. Among the enzymes the diastase may approach zero while the trypsin remains within normal limits. This is referred to as type 1 disturbance. Another pathologic group may show a correlated diminution of all pancreatic functions. This is referred to as type 2 disturbance. Combinations

of both types may exist. Type 1 is characteristic of acute pancreatitis. The functional disturbance is reversible and in most cases recovers completely. The pathologic basis for the disturbance probably need not be more grave than toxic-inflammatory edema. Type 2 disturbances may occur in any disease of the pancreas, rarely in acute pancreatitis. The simplest interpretation of this disturbance is a reduction in amount of functioning pancreatic tissue, diffuse or regional. There may be destruction of pancreatic cells from different causes (cirrhosis, necrosis or carcinoma) or obstruction of pancreatic ducts (by edema, tumor or calculus). The practical diagnostic value of the secretin test is demonstrated by the distribution of the amounts of bicarbonate in forty-one normal subjects, compared with twenty-five patients with pancreatitis, three with pancreatic calculi and four with cancer of the pancreas. The normal bicarbonate elimination during sixty minutes, following the intravenous injection of the standard dose of secretin, presents a mode of 150 cc. of tenth normal bicarbonate solution. The demarcation between low normal values and pathologic subnormal values is definite. A tendency toward subnormal values is clearly demonstrated in the pathologic material. Secretin tests have been done on twenty-two diabetic patients. Two had pancreatic calculi, one cancer of the pancreas and one a very severe acute pancreatitis. Of the remaining eighteen, none had any other sign of pancreatic disease than the diabetes. These patients had a lower average bicarbonate elimination than normal, in ten the amounts were significantly lower, in three the values were on the borderline of normality. The diastase elimination resembled the bicarbonate. Eight patients showed definitely subnormal values, five borderline values. The low values of diastase do not depend on elevated blood sugar levels.

Agglutination of Virus-like Particles.—Eagles and Bradley tested the serums for agglutination in eighteen cases of rheumatic fever, twenty cases of arthritis of the rheumatoid type and sixteen cases of arthritis of the rheumatoid type of known etiology (i. e., gonococcal and pneumococcal arthritis), gout or joint disease not of the rheumatoid type. Serum was obtained by the usual method, stored at 4 C. and used for agglutination tests as soon as possible. To avoid lipid in the serum, blood was taken between 10 a. m. and the noon meal. Agglutination was not confined to serums from rheumatic fever and rheumatoid arthritis but occurred with serums from the sixteen cases of other arthropathies in which any relationship to true rheumatism was remote. There is no significant difference in the occurrence of agglutination in any of the three types of serums. Agglutination tended to occur most frequently in serums taken during the active phase of acute rheumatic fever and acute rheumatoid arthritis but was by no means so limited. Agglutination was not confined to the phase of recovery but occurred during other phases as well, making it impossible to draw any definite conclusion that agglutination and clinical episodes are intimately related. Elementary body agglutination did not depend on the presence of *Streptococcus pyogenes* in the throat, nor did it necessarily occur after acute infection with *Streptococcus pyogenes* even when an attack of acute rheumatism was unquestionably related to the throat infection. In one instance, however, the simultaneous appearance of the ability of the serum to agglutinate rheumatic suspension at the onset of rheumatic fever following an acute infection of the throat was particularly striking. No reason for this in this single case is offered. Intercurrent *Streptococcus pyogenes* episodes were observed during hospitalization in six of the fifty-four cases studied. The streptococcal immunologic observations in all six patients were undoubtedly influenced by these infections. Three of these had acute rheumatic fever (in two of which acute exacerbations of rheumatism developed subsequently), one had focal arthritis and two had other arthropathies. Assuming elementary body agglutination and antistreptolysin to be unrelated, the calculated expectation in the present series is that thirty of any 110 samples would show no evidence of streptococcal infection. There is, therefore, no evidence for a specific causal relationship between agglutination of rheumatic elementary body suspensions and streptococcal infection. There is no evidence that agglutination is dependent on or influenced by conditions governing increased sedimentation rate or pyrexia. This confirms the earlier observations of other investigators.

Surgical Treatment of Diabetes by Biliary Deviation.

—Leriche and Jung say that in the course of experiments carried out previously on the deviation of the bile they were surprised to find on microscopic examination of the pancreas that the endocrine cells appeared to be more numerous, more distinct, heavier and more active. Starting from that, they decided to make new studies on biliary deviation with respect to the problem of insulin. They produced total deviation of the bile in seventeen adult dogs. They sectioned the choledochus, ligated the inferior end and into the superior end introduced a small glass cannula mounted on a short india rubber drain. When the choledochus was too thin to lend itself to this, it was tied and the cannula was fixed into the gallbladder. The inferior end of the drain was introduced into the bladder. Studies were made on the blood sugar. The dogs died or were killed after from six days to four months. Microscopic studies on the pancreas revealed that the endocrine cells were especially clear; the island presented pronounced vascular congestion and large nuclei of greater than normal density. The authors also describe the history of a woman with diabetes mellitus in whom deviation of the bile was maintained for thirteen months by a fistula with an external opening. In the concluding summary they say that their observations do not justify the recommendation of this form of surgical treatment for patients with diabetes mellitus. Nevertheless, their studies revealed several factors which indicate that the endocrine activation of the pancreas is possible by deviation of the bile. They emphasize the following factors: 1. In animals the biliary deviation leads to microscopic modifications of the pancreas which indicate activation of the endocrine glands and irregular or diminished activity of the exocrine gland. 2. During the biliary deviation the blood sugar content of the animals is generally low. 3. Sugar tolerance tests produce lower blood sugar curves in these animals than in the controls. 4. In the woman whose case history is reported the glycemia during the thirteen months of biliary deviation was maintained at values between 1.67 and 1.95 without having need of insulin, although before the glycemia was 3 in spite of the administration of from 80 to 100 units of insulin daily. The authors think that it would be advisable to study experimentally and clinically a definite deviation of the bile by cholecystojejunostomy. If this procedure is efficacious, it will be more simple than splanchnicotomy, adrenal ablation or denervation of the liver.

*Technic of Surgical Treatment of Calculus of Choledochus. L. Gidró.—p. 308.

Surgical Treatment of Calculus of Choledochus.—Gidró does not consider it necessary to open the choledochus in all cases of lithiasis of the gallbladder, but he is in favor of careful examination and frequent exploration by the sound. He recommends exploration by the sound (1) if there are clinical symptoms of occlusion (icterus in the absence of occlusion), (2) if calculi can be palpated in the principal biliary passages, (3) if the choledochus is larger than ordinary, (4) if the choledochus or its surroundings show signs of inflammation, (5) if the cystic duct is so large that passage of the calculus into the choledochus is possible, (6) in cases of acute inflammation of the gallbladder and (7) if the patient had icterus before he had pains. If the principal biliary passages are not detectable, it

must be assumed that there are calculi in the choledochus. In the latter case the author recommends retrograde exploration, that is, by way of the duodenum. He does not open the choledochus during exploration but if possible enters the choledochus by way of the cystic duct. The result of the exploration of the choledochus determines the further surgical procedure. In case of negative results, after the cystic duct is cut, it is ligated or sutured and, unless the bile is not infected, cholecystectomy is performed. If calculi are found, it is not by choledochotomy but through the cystic duct with forceps and curet that the author removes the mobile biliary calculi, the great majority of which do not exceed the size of a hazelnut. If the cystic duct is large enough, they can be made to glide out. The author employs this procedure more and more frequently. During 1936-1937 he used it in 55 per cent of the cases of lithiasis of the choledochus. He used exploration by the cystic duct in thirty-eight cases, and in twenty of these cases one or several choledochal calculi could be removed. The advantages of exploration and of lithectomy by way of the cystic duct consists on the one hand in that it makes choledochotomy avoidable and on the other hand in that it is a more aseptic and a shorter operation than is choledochotomy. That lithectomy by way of the cystic duct is not dangerous, the author demonstrates by citing the mortality rates of different operations: 1. Choledochotomy with drainage of the choledochus caused six deaths in thirty-two cases (mortality 18.75 per cent). 2. Choledochotomy with primary suture of the choledochus (choledochorraphy) caused four deaths in twenty-two cases (18 per cent). 3. Exploration and lithectomy by way of the cystic duct (transcystic lithectomy) did not cause a single death in thirty-eight cases. The author performs supraduodenal choledochotomy if exploration or lithectomy by the cystic duct is not possible and calculi are found in the hepatic canals. He chooses retroduodenal choledochotomy if a calculus is found in the lower part of the choledochus or at the duodenal papilla. He resorts to transduodenal or intraduodenal choledochotomy if, because of adhesions and cicatrices, the choledochus cannot be found by other means. He drains the choledochus only in the following cases: if before or at the time of the operation there exists septic fever, if the bile contains much pus, if functional examination of the liver indicates grave parenchymal alterations, and finally if apart from the presence of choledochal calculi acute inflammation of the gallbladder exists.

*Tetanic Anatoxin and Prophylaxis of Tetanus in Man and in Domestic Animals. G. Ramon.—p. 877.

Physiologic and Therapeutic Actions of Cynara Scolymus. L. Tixier.—p. 880.

Chronic Edema of a Lower Extremity. L. Ramond.—p. 887.

Prophylaxis of Tetanus.—Ramon shows that vaccination by means of tetanus toxoid is applied in individual persons and in groups who are especially exposed to tetanic infection. The active immunity engendered by the toxoid of tetanus assures permanent protection against the risks of tetanus, risks which may result either from open injuries or from insignificant wounds the benign character of which does not demand the injection of antitetanic serum, or finally from the existence of tetanigenous foci which give no sign of their presence. The diffusion of antitetanic vaccination can be greatly facilitated by associated vaccinations which make it possible to unite tetanus toxoid with one or several vaccines that are already in current use, for example, diphtheria toxoid or antityphoid vaccine. The vaccination by tetanus toxoid according to the formula of associated vaccinations provides the most favorable conditions for the systematic prophylaxis of tetanus in the individual as well as in groups. In the French army this method has been employed for several years and it is being adopted in other armies as well. The practice to vaccinate domestic animals, particularly horses, with tetanus toxoid has provided the opportunity to furnish the indisputable proof of the efficacy of this vaccination. Since 1927 extensive use has been made of this method of prophylaxis on the horses of the French army and as a result tetanus has disappeared. A single, nonfatal case was observed during 1937. On the basis of information

obtainable so far, vaccination with tetanus toxoid seems to be the method of choice for the prophylaxis of tetanus in human subjects and in domestic animals susceptible to this toxoinfection.

Serodiagnosis of Tuberculosis During Preallergic Period. P. Courmont.—p. 614.

Silicosis in Gold Miners.—Amsler and Cady studied the pulmonary aspects of workers in different mines, because in their region not only slate is mined but also ferrous and auriferous ores. Whereas the percentage of free silica in slate is comparatively low (from 6 to 7 per cent), the compact white quartz which constitutes the auriferous veins contains from 60 to 80 per cent of silica and this explains the variety of forms of silicosis that are encountered in the workers who extract and crush or otherwise manipulate the ore. The authors observed the successive pathologic phases of silicosis. Most of the workers who came under their observation on account of silicosis were of the age group between 25 and 40; generally they were robust and had always been in excellent health. The family histories were usually free from tuberculosis. Some had worked in the mines for many years, others only for about five years. Occasionally they came for examination because they had been aroused to the dangers of their occupation by the rapid deaths of some of their co-workers. A man aged 31 had worked in the gold mines for five years and had no symptoms. The pulmonary auscultation and roentgenoscopy revealed nothing abnormal, but roentgenography revealed considerable changes. There was a dissemination of micronodular images in both lungs. The volume of these nodules is slightly greater than that of tuberculous granulations and their opacity is likewise greater. The general aspects of these miliary images give the impression of a snowstorm. The patient had no spontaneous expectoration. Induced expectoration never disclosed tubercle bacilli. The phase of silicosis presented by this patient is the initial one, which may be designated as latent or preclinical. It is demonstrable only by roentgenography. From personal observations the authors conclude that this typical aspect is observable at the end of about five years. Later the subject develops a dry cough or one that is accompanied by mucous expectoration. Sometimes this is associated by emaciation and fatigue and by thoracic pains that are augmented by cough and respiratory effort. The examination with the stethoscope is frequently negative or reveals only the signs of pulmonary emphysema and sclerosis. The disorder may remain in this phase for months and even for years with occasional exacerbations in the functional signs. If the patient stays away from the mine and rests for several months, the development of the silicosis ceases; it is arrested and then it regresses, but the spots in the lungs persist for a long time. In other miners, however, the symptomatology is constant and gradually dyspnea develops; the patient becomes emphysematous and develops cardiac decompensation; he becomes constantly weaker and is hardly able to walk, and the smallest effort is difficult and painful. The auscultation still reveals only emphysema and bronchitis, but roentgenography reveals new nodules, retractile sclerosis and irregular spots. Expectoration becomes more profuse and coughing is persistent. This status represents the pseudotumoral phase of silicosis. The authors describe a case of this type and then discuss the terminal stage with its complications, such as spontaneous pneumothorax, and again relate typical case histories. In the last part of their report they take up the concurrence of silicosis and tuberculosis, pointing out that in some miners they were able to observe the evolution of tuberculosis in silicotic lungs. The tuberculous lesions of gold, iron and slate miners present such characteristic modifications that it may be possible to identify these miners on the basis of the roentgenographic aspect of their thorax.

Epidemic Appearance of Catarrhal Icterus.—Bloch says that it is well known that the so-called catarrhal icterus occasionally occurs in small epidemics. Reports about such epidemics have appeared especially since the last war. In the literature to which the author had access he found forty reports about such epidemics, in all of which it was possible to exclude Weil's icterogenic spirochetosis. He describes observations that were made in the course of one epidemic which broke out in a work camp of students. Of 115 students twenty-seven, or 23 per cent, developed catarrhal icterus. Further he reviews reports about several other epidemics of catarrhal icterus and discusses the various aspects of the disease. He reaches the conclusion that epidemic catarrhal icterus is an infectious and contagious disease *sui generis*. A causal organism has not been detected as yet, but *Leptospira icterohaemorrhagiae* can be excluded. The transmission is usually effected by personal contact, less often by drinking water. The period of incubation is from two to four weeks. The clinical course largely resembles that of simple icterus. It could not be proved that an attack of the disorder produces a specific immunity. Epidemic catarrhal icterus appears chiefly during the last part of the summer and during the fall and mostly among groups of children and soldiers. The author considers it possible that sporadic and epidemic catarrhal icterus are identical diseases; there are some relations to yellow atrophy of the liver.

*Bronchiectasis in Children. A. Casaubon.—p. 501.

Bronchiectasis with Abscess. A. Segers and A. Russo.—p. 567.

Bronchiectasis in Children.—Casaubon observed twenty cases of bronchiectasis in children. The disease may be either congenital or acquired. In all cases a constitutional hereditary factor and especially the presence of congenital syphilis are important determining factors. A clinical diagnosis is made by (1) the history of the patient (showing repeated or prolonged respiratory infections with bouts or else whooping cough), (2) the results of repeated auscultation (by which wet rales are heard in fixed zones of the lung, especially at the base, and which diffuse during the bouts) and (3) the elimination of abundant expectoration which does not contain tubercle bacilli. The symptoms are acute and similar to those of pneumonia or bronchopneumonia in cases of extended bronchiectasis or during an exacerbation. A simple x-ray examination of the chest may in certain cases be of diagnostic value, by showing a juxtahilar triangular or right angular shadow toward the base, which is frequent (although not pathognomonic of) bronchiectasis. In the presence of bronchopulmonary sclerosis the diagnosis is made by bronchography. The bronchographic images of bronchiectasis may be cylindric, moniliform, finger-like, ampullar, sacciform and in the forms of nests, bunches of grapes and lakes. Cylindric and generalized bronchiectases originate in the bronchial mucosa, whereas ampullar and sacciform bronchiectases are due to retractile sclerosis from lesions of the lung parenchyma, of the pleura or of both structures. The coexistence of bronchiectasis and other malformations of the respiratory tract, as verified by bronchography, indicate the congenital origin of bronchiectasis in the given case. The bronchographic image of the normal respiratory tract is similar to a tree in summer, that of bronchiectasis is similar to a tree in winter (lack of visualization of the alveoli). In cases of agenesis of the small bronchi and of the alveoli the image is that of a pruned tree. The bronchographic aspect of a bronchiectatic abscess of the lung depends on whether the abscess forms before or simultaneously with bronchiectasis. In latent and chronic bronchiectasis in syphilitic or suspected syphilitic patients the administration of antisyphilitic treatment is indicated. A complementary treatment for

syphilitic and nonsyphilitic patients during the latent and chronic stages of the disease consists in giving the patient certain respiratory exercises, living in a dry, warm climate, preventing infections and removing septic (especially buccopharyngeal) foci and foreign bodies if there are any in the respiratory passages. During the bouts the treatment is symptomatic, similar to that which is resorted to in pneumonia and bronchopneumonia and including autovaccines or heterovaccines. The surgical treatment is indicated in acute bronchiectasis, especially when complicated by abscess of the lung.

Influence of Dihydrotachysterol on Lens During Tetany.—According to Rauh it has been demonstrated clinically as well as experimentally that typical forms of gray cataract develop as the result of postoperative and of idiopathic tetany. Holtz's discovery of the therapeutic effect of dihydrotachysterol in tetany raised the question whether the characteristic opacities of the lens as well as the fully developed cataract of the tetany can be influenced by dihydrotachysterol. The author decided to investigate this problem on animals. The course of development of the cataract of parathyroid tetany having been thoroughly investigated in rats, he decided to study the effect of dihydrotachysterol in these animals. He reports his observations on seventy-seven animals. Since in young rats the postoperative tetany takes a rather rapid course and the changes on the lenses are especially uniform, he chose animals which weighed less than 100 Gm. The observations on the lens were made with the slit lamp; the dihydrotachysterol was given with the food. Careful records were kept about the quantities of dihydrotachysterol administered to the animals as well as about the condition of the lenses. The author describes and illustrates some of the turbidities of the lens. In the course of three years he studied the effect of dihydrotachysterol under various conditions. He was able to demonstrate that tetany and the lenticular opacities of tetany can be prevented by means of dihydrotachysterol. Moreover, opacities of the lens subside under the influence of dihydrotachysterol until the lens is practically clear again; however, in order to retain this clarity of the lens the medication with dihydrotachysterol must be continued, because after it ceases the opacities return again. The author says that Meesmann's studies on the changes of the lens during hypocalcemia in human subjects correspond to those in animals; however, there is as yet no record of the disappearance of the turbidities in human subjects. Nevertheless the administration of dihydrotachysterol promises a successful prophylaxis of the cataract of tetany. The decision as to what degrees of opacities will be amenable to treatment with dihydrotachysterol will require further observations. The author emphasizes that of course only the cataract of tetany but not that of old age can be treated with dihydrotachysterol.

Early Operation of Umbilical Hernia. H. Tomberg.—p. 702.

Prevention of Arteriosclerosis.—According to Raab, necropsies have disclosed signs of beginning arteriosclerosis in a surprisingly large proportion (83 per cent) of persons between 20 and 30 years of age and severe forms of arteriosclerosis in from 21.4 to 36.8 per cent of persons beyond the age of 40. Enumerating the pathogenic factors of arteriosclerosis that are amenable to prophylaxis, the author shows that many of them

have one factor in common in that they have some relation to the adrenal function. From the cortical lipoids and from epinephrine the adrenals form a substance which is capable of impairing the arterial walls not only directly by degeneration of the media and loosening of the intima but also indirectly by favoring the deposition of the cholesterol that circulate in the blood. There seems to be a hereditary predisposition to increased production of this factor in the adrenals and to the susceptibility of the vascular walls to its action. The anterior lobe of the hypophysis promotes the function of the adrenals, whereas the gonads have an inhibiting effect. Moreover, it is known that mental strains of various types promote the secretion of epinephrine. Further attention is called to the role of the lipid content of the food, of the activation of ergosterol by light and of the abuse of nicotine in the pathogenesis of arteriosclerosis. The author stresses that in order to reduce the incidence of arteriosclerosis the following factors deserve attention: 1. The intake of egg yolks, butter fat and animal fats should be limited; that is, these substances should not supply more than from 10 to 15 per cent of the total calories. The diet should consist chiefly of cereals, fruits and vegetables. 2. Abuse of nicotine should be avoided. 3. Attention should be called to the harmful effects of excessive exposure to the rays of the sun. 4. Persons who are especially exposed to arteriosclerosis (those with hypertension, stenocardia, cardiac insufficiency and intermittent claudication) could be subjected to periodic roentgen irradiation of the adrenals and perhaps also of the hypophysis. Moreover, the administration of gonadotropic substance might prove helpful. 5. Marriage between persons with hereditary predisposition to severe arteriosclerosis should be discouraged. 6. Mental strain and excessive excitement should be avoided.

Treatment of Vesical Tumors.—Heckenbach differentiates between papillary and solid tumors. The papillary tumors may be papillomas or papillary carcinomas, but the clinical course of these two types of tumors does not differ greatly. The author has been able to remove papillary carcinomas by endovesical coagulation. A papillary tumor, no matter whether a papilloma or a papillary carcinoma, provides favorable therapeutic conditions. Both types represent projecting, more or less voluminous tumors that are attached by means of a pedicle, which, whether narrow or wide, involves only the surface; that is, it is limited to the mucosa. Moreover, the papillary tumors do not have a tendency to grow deeper. The author thinks that the decision to resort to endovesical treatment must be based chiefly on the localization and the size of the papillary tumor. It must be possible to remove the tumor entirely and without great damage to the surroundings and particularly to the deeper layers of the vesical wall. Endovesical treatment should be employed only if it promises success. To attempt endovesical treatment and in case of failure resort to opening of the bladder the author regards as inadvisable, because this procedure may lead to unexpected complications. Endovesical coagulation may produce an ulcer that is refractory to all treatment and which often represents the beginning of an infiltrating carcinoma. Thus if there is no hope that a tumor will be completely removed, the method in question is not only unjustified but even dangerous. This applies not only to endovesical coagulation but also to operations with opening of the bladder. In case of small tumors, the surgical opening of the bladder has no advantages over the endovesical procedure; on the contrary, it may lead to dissemination. The papillomas at the internal sphincter are not suitable for endovesical interventions. The author treats these with the same instrument that is used for the electroresection of the prostate. If, in papillary tumors that involve only the mucosa, surgical opening of the bladder is necessary, the operation should be done from the side of

the lumen, for resection of the entire vesical wall is unnecessary in papillary tumors. In cases of solid and infiltrating tumors that involve all layers of the bladder, the endovesical treatment is an inexcusable mistake; in such cases whole sections and surfaces of the bladder must be resected. In their effect on the upper urinary passages, papillary and solid tumors show an entirely different behavior, which, however, is so characteristic for both types of tumors that roentgenologic examination and elimination urography provide valuable diagnostic and therapeutic suggestions. The author found that papillary tumors, even if they are comparatively large, cause insignificant or no changes. He reproduces a roentgenogram of one case in which a giant papillary tumor filled almost the entire vesical lumen. In spite of this large papillary carcinoma the upper urinary passage was unchanged, and complete cure resulted following removal of the growth. Since typical manifestations in the upper urinary passages appear, particularly in case of the infiltrating tumors, at a time at which the instrumental examination provides as yet no insight into the nature of the disease, the x-ray examination facilitates the early diagnosis.

Passive Renal Congestion from Supernumerary Vessels.—Riester says that the passive congestion of the kidney which is caused by supernumerary vessels that radiate toward the lower pole and cross and bend the ureter has been a well known clinical entity since its description by Ekehorn in 1907. Most of the reports about this disorder which have appeared since then concerned cases in which the passive renal congestion was completely developed. In these cases usually the renal parenchyma is largely or completely destroyed and the function is impaired to such an extent that the diseased organ must be removed. However, as was pointed out by Ekehorn, the aim should be the early recognition and the prompt removal of the obstruction before a large hydronephrotic sac has developed and while the functional capacity of the kidney is still preserved. The author says that efforts were made at his clinic to detect the disorder in its early stages. In the course of these studies it was found that during the early stages the disorder presents an extremely varied picture; there are no characteristic changes, and intraperitoneal disorders are frequently simulated. At the first appearance of symptoms, neither the urologic nor the x-ray examinations disclose pathologic changes. Systematic observations and the repetition of examinations at certain intervals revealed that a gradually developing passive congestion of the kidney at first can be determined only by x-ray examination. Demonstrable functional impairment appears much later, in a rather advanced stage of the disorder. Only the comparison of several roentgenograms of the renal pelvis made successively at certain intervals make possible a correct interpretation of the slight pathologic changes. The author reports the clinical histories of two patients with passive renal congestion. Both patients complained at first about indefinite abdominal pains. After a time, both had colic-like attacks. Indigo carmine tests of the renal function produced normal results throughout the entire period of observation. The patients were unable to localize the pains and colics. Sinking of the kidney, resulting from loss of fat, caused the ureter to ride on the vessel and later produced bending. To be sure, the presence of a supernumerary vessel is a prerequisite. According to Petren, this is a comparatively frequent anomaly. The severity of the symptoms is dependent on the degree of renal descent. The renal congestion of the first patient was preceded by a considerable loss of weight; the loss of fat of the second patient, a youth aged 19, may have been caused by growth. After describing interesting observations on the

roentgenograms of these patients, the author stresses that early recognition and a prompt surgical intervention will not only counteract the symptoms but also preserve the function of the involved kidney.

Hydrochloric Acid in Preoperative Cleansing of a Cancerous Stomach.—According to Abramovich, peritonitis was the cause in 72 per cent of the 132 fatalities following the operation for gastric cancer at the Leningrad Oncologic Institute. Friedrich in 1933 adopted for patients about to be operated on for gastric cancer a method of administering diluted hydrochloric acid and washing the stomachs with 0.25 per cent hydrochloric acid. The author reports a bacteriologic study undertaken to determine the effect of this treatment on the bacterial flora of the gastric contents. Sixty-four patients with gastric achylia about to be operated on for gastric tumor were given a tablespoonful of diluted hydrochloric acid in a glass of cooled boiled water three times daily. Their stomachs were washed daily with large quantities of cooled boiled water followed by from 0.5 to 1 liter of 0.25 per cent solution of hydrochloric acid. These studies demonstrated that the anacid gastric contents of gastric cancer patients are never sterile. The oral administration of diluted hydrochloric acid in the course of several days before the operation destroyed certain types of micro-organisms and diminished the number of colonies of other types. Drinking of the solution combined with the lavage accelerated the cleansing process. The maximum bactericidal effect was accomplished in from thirty to sixty minutes, after which period the bacteria increased in numbers. The author suggests, therefore, that hydrochloric acid lavage be practiced immediately before the operation. While the author realizes that the primary factor in the reduction of the postoperative mortality is the proper choice of operation and adequate technic, he believes that partial reduction of pathogenic micro-organisms of the gastric contents may be regarded as an additional factor in reducing the postoperative peritonitis.

Results in Addison's Disease from Transplantation of the Adrenal Cortex.—According to Auslender, administration of epinephrine in cases of Addison's disease gave no results and frequently failed to raise the blood pressure. Because of dyspeptic disturbances, most patients did not tolerate the feeding of raw adrenal. Administration of adrenal cortex extract was effective in the milder cases as long as it was administered, the symptoms promptly returning on its withdrawal. A number of fatalities are recorded in the literature following both hetero-transplantation and homotransplantation of the whole adrenal. Erdheim believed from evidence in one necropsy that the transplanted adrenal of man rapidly underwent necrosis. Believing that necrosis always begins in the adrenal medulla, the author performed twenty-seven transplantations into animals of both the whole adrenal and of the cortex at the same time. The whole adrenal transplants invariably did not take and suppurated, whereas the cortical transplant took and retained its morphology for as long as four or five months. The author reports the immediate and the late results of twenty transplantations in fourteen cases of Addison's disease. The adrenal was removed immediately on the killing of the animal at the abattoir and the cortex was dissected from the medulla in the operating room. Fragments of the cortex were implanted into the subcutaneous tissue of the abdomen. The immediate results were excellent in all of the fourteen cases. The patients exhibited an increase in weight, in the blood pressure, in the blood cholesterol and in the blood sugar, as well as an increase in the muscle power. Nausea, vomiting, diarrhea and low gastric acidity disappeared. The general health was improved to such a degree that patients who were invalids for one to two years were able to resume their occupations. More or less

permanent results were obtained in the mild cases and in the cases of medium severity. The longest period of observation was one year and eight months. In a few cases the improvement was progressive. In the severe cases the improvement lasted from five to six months, after which there was a gradual return of the symptoms, necessitating in from nine to twelve months a second transplantation. These second transplantations gave equally good results. The author concludes that the transplanting of the adrenal cortex is superior to any of the therapeutic measures in Addison's disease.

*Death by Hypoglycemia During Treatment with Protamine Zinc Insulin. J. Groen and A. H. Garrar.—p. 1844.

Hypoglycemic Death from Protamine Zinc Insulin.—Groen and Garrar give a detailed clinical history of a woman, aged 27, who had had diabetes since the age of 12 and who had received insulin since the age of 15. When she was admitted to the hospital she was unconscious. She was in the eighth month of pregnancy and it was learned that two weeks before she had been discharged from another hospital, where her insulin treatment had been changed so that one daily injection would be sufficient. At the time of discharge from the hospital she was free from sugar. At 6:30 in the morning she took 12 units of ordinary insulin and 52 units of protamine zinc insulin. After her discharge from the hospital she had several attacks of hypoglycemia. On the day when she was brought to the hospital her husband had left the home at 5:30 a. m. A friend, who called at 8 a. m. to accompany her to the clinic, was not admitted and left without further investigation. The husband, who returned at 6:30 p. m., found his wife unconscious. When the doctor, who was called, learned that the woman had diabetes, he injected 20 units of insulin and then sent her to the hospital. When she arrived, the respiration was not of the Kussmaul type and there was no odor of acetone. The urine, which was obtained by catheterization, did not contain protein, sugar or ketone bodies. The blood pressure and temperature were normal. Diabetic coma and eclamptic coma could be ruled out. While a blood test was being made the patient died and attempts at revival were without avail. The blood was found to contain only 20 mg. of sugar per hundred cubic centimeters. The authors think that it cannot be doubted that death had been caused by hypoglycemia. They stress that attention must be given to the instability of the blood sugar content of pregnant women who receive insulin therapy. They think that during the final months of pregnancy these women should remain in the hospital so that constant supervision is possible. Moreover, protamine zinc insulin should not be given in large doses; they consider quantities exceeding 40 units too large. They also warn against the thoughtless administration of insulin to every unconscious diabetic patient. Insulin should be administered only if symptoms of diabetic coma are actually present, such as Kussmaul's respiration, acetone odor of the breath and presence of sugar and acetone in the urine. As another important factor the authors stress that diabetic patients themselves as well as a person living with them should have some knowledge of the symptoms of hypoglycemia. As far as the authors were able to ascertain, this was the eighth case in which protamine zinc insulin has been either the main or a contributory cause of death.

*Clinical-Experimental Studies on Hormonal Regulation of Fat Resorption: Case of Addison's Disease with Change of Fat Tolerance Curve Following Administration of Adrenal Cortex Extract. E. Westerlund.—p. 1065.

Endocrine Regulation of Fat Resorption.—Westerlund believes that insufficiency of the adrenal cortex is a factor in the pathogenesis of the steatorrhea which may accompany Addison's disease. He describes a case in which there were

pathologic amounts of fat in the feces. Administration of fat before the start of treatment with adrenal cortex extract showed a low fat tolerance curve. On repeated administration of fat after one injection of the extract and after protracted administration of the extract the fat tolerance curves were considerably higher.

Acute Asthmatic Attack with Suffocation in Child: Tracheotomy, Bronchial Catheterization. K. H. Køster.—p. 1251.

Death Due to Asthma.—Jørgensen says that in adults fatal asthma manifests itself by predilection in the bronchi, in children in the pulmonary parenchyma, where the predominant change is plasmatic exudation in the alveoli, and that the two types of reactions may be regarded as different manifestations of the same disturbance. In the fatal case reported, in a man aged 44, they appeared side by side. The allergic pulmonary infiltration, the structure of which is unknown, may consist of a massive plasma exudate in the alveoli.

Paroxysmal Granulocytopenia (Sundelin). A. Nyfeldt.—p. 443.
Case of Osteomalacia. T. Gimsing.—p. 444.

Constriction of Heart.—Warburg describes five cases of "pure" constrictive pericarditis treated operatively, with good results in three cases and no deaths. He says that the syndrome is rare and the etiology unknown. Rheumatic fever is not believed to be a factor. The most important symptoms are swelling of the veins of the neck, even when the patient is seated, marked increase in venous pressure, stasis of the portal vein with enlargement of the liver and ascites; and in the "pure" cases a small heart. The electrocardiogram was abnormal in eight of the nine cases and seemed to be characterized by inversion of the T deflection. There was low voltage in only two cases. The author asserts that the disorder is probably present in young patients with stasis of the portal vein and increased venous pressure if valvular defects and arrhythmias are excluded, and that diagnosis is simple when this is borne in mind. Establishment of gallop rhythm supports the diagnosis.

*Streptococcus Meningitis, Streptomide and Pyrimide (Sulfapyridine). O. Kirstein.—p. 496.

Effect of Sulfapyridine in Type III Pneumococcus Pneumonia.—Alsted says that, of six patients with lobar pneumonia of type III, all but one over 60, treated with a dosage of from 12 to 33 Gm. of sulfapyridine, normal temperature was reached in from three to twenty days. Apart from a slight nausea and vomiting there were no toxic manifestations. Two cases of bronchopneumonia were fatal in spite of treatment with sulfapyridine.

Streptococcal Meningitis, Streptomide and Sulfapyridine.—Kirstein describes the case of a girl, aged 13, in whom a grave acute meningitis, due to nonhemolytic Streptococcus bovis, developed after a lesion of the eye. Intraspinal and oral treatment with sulfanilamide had only a transitory effect. On the thirty-fourth day, when the patient seemed moribund, oral administration of sulfapyridine was begun. In a few days the clinical symptoms of meningitis disappeared, and in five weeks the patient was discharged, apparently well.

CHRONIC INTRACTABLE ULCERATIVE COLITIS—A SURGICAL PROBLEM

CHAIRMAN'S ADDRESS

HENRY W. CAVE, M.D.

NEW YORK

Failure of conservative, or medical, measures is leading to surgical intervention in an increasing number of cases of chronic ulcerative colitis. Clinicians who have had extensive experience with the disease are at present prone to be cautious in accepting the term "cure." Many forms of treatment have been recommended—rest in bed, high caloric, high vitamin, low residue diets, vaccines, serums of various types, including antistreptococcus, anticolon bacillus and antidyentery, sulfanilamide and other chemical agents, blood transfusions and medicated irrigations. Not infrequently, certain of these measures are followed by temporary improvement. Less often is the improvement sustained. Usually the cycle of the disease continues and progressing pathologic change thwarts the efforts of the physician and destroys the health and usefulness of the patient. "It is impossible to say that after any given period of freedom from activity the disease will not recur."¹ Certainly in the past many patients have been lost because radical surgical measures were denied them.

It may be stated generally, however, that surgical intervention should be delayed until two factors have been evaluated: (1) the response to conservative treatment and (2) the extent and distribution of permanent damage to the colon.

During the past three years my associates and I have had an unusual opportunity to study intensively many cases of ulcerative colitis. A specially equipped laboratory and a clinical service have been established for investigating the mechanism of this and allied diseases. Two hundred and fifty-seven patients have been carefully studied, classified and followed by Dr. Thomas T. Mackie and his medical associates, some for as long as seven years; 158 of these have been treated in the Gray service of the Roosevelt Hospital. Twenty-seven of the latter group have been subjected to surgical intervention. It is from this experience that the title of this paper has been derived. We have as well ascertained certain facts and have formulated conclusions which appear worthy of presentation.

An attempt has been made to divide, although somewhat empirically, these patients into four classes: (1)

those with a mild form, arrested and perhaps cured by medical management alone (this class is excluded from the discussion); (2) those with the acute fulminating, often fatal form; (3) those with the chronic continuous form, and (4) those with the chronic form with remissions, which is frequently intractable.

There is little unanimity of opinion concerning the indications for elective operation. There are few criteria for determining operability. These two fundamental problems at times are difficult of solution, yet they must be solved if successful results are to be achieved. The former depends on the local pathologic change, the latter on the general condition of the patient as well as on the pathologic change.

The disease is characterized by inflammation and ulceration of the colon, cellular infiltration and marked production of scar tissue. This process commonly extends with each exacerbation and recurrence of the disease, producing progressive permanent damage and dysfunction, until ultimately the colon becomes transformed into a narrowed and shortened fibrotic organ lined with infected granulation tissue. When this stage has been reached, the term intractable may be applied. The effort to restore the patient to health then becomes a definite problem of elective surgical intervention.

The choice of operative procedures must be based on the extent and situation of permanent damage to the colon. These can be determined with considerable accuracy by the combination of proctoscopic examination and careful x-ray examination. The roentgenograms reveal the characteristic shortening, narrowing of the lumen, absence of haustral markings, mucosal destruction and pseudopolypoid degeneration. When the entire organ is involved, the normal angulations at the flexures tend to approximate right angles. The barium sulfate enema demonstrates a rapidly filling colon, with hyperirritability of the segments that are involved.

Perforation, impending or actual, multiple cutaneous infections and the frequently occurring and recurring perirectal abscesses naturally require immediate operation. In view of recent disastrous experiences with four fatal cases of the acute fulminating form, it seems probable that complete diversion of the fecal stream should be carried out much earlier than is usually done.

Criteria of operability are difficult to define in many conditions. They are particularly so in chronic ulcerative colitis, a disease commonly complicated by profound physiologic disturbances, including change in the plasma protein and electrolyte concentrations, inanition and marasmic states, advanced grades of vitamin deficiencies, disturbance of fluid balance and severe and refractory anemia, all of which profoundly affect the surgical mortality.

From the Gray Service, the Roosevelt Hospital.

J. A. M. A. 111:2071 (Dec. 3) 1938.

PREOPERATIVE PREPARATION

The decision to resort to operation, therefore, does not mean that medical supervision should cease. I cannot emphasize too strongly the importance of meticulous preoperative and postoperative medical control. Preparation for operation is frequently time consuming. Blood chemistry and blood vitamin determinations are made at frequent intervals. Anorexia and its effects are combated by heavy parenteral doses of thiamin chloride and at times by continuous gavage feeding of a calibrated synthetic diet. Dosage of the other vitamins, controlled by weekly or biweekly blood vitamin assays, is pushed until the curves at least approximate normal. Supplemental mineral salts are added when

the content of blood electrolytes is low. The frequent finding of lesions of the mouth and tongue of the pellagra type is considered an imperative indication for the administering of nicotinic acid and of liver extract parenterally. The anemia is corrected by iron or liver extract and transfusion. In addition, abundant dextrose in saline solution given intravenously is essential. The preoperative diet should be low in residue. Daily cleansing colonic irrigations of physiologic solution of sodium chloride are given, and for two days prior to operation lead and opium pills and camphorated tincture of opium are administered in order to shrink the colon, thus simplifying the technical procedure.

ANESTHESIA

Complete relaxation is necessary during the stage when the entire colon is removed. Heretofore, avertin in amylene hydrate and cyclopropane have proved satisfactory. In view of recent catastrophes, I question whether this highly explosive gas should be used as a routine. Spinal anesthetics in the form of procaine hydrochloride, or preferably pontocaine hydrochloride and nupercaine for their prolonged continuous action, may be used with relative safety. It matters little what is used at the first stage of ileostomy. I do believe, however, that ether is contraindicated during the stage of colectomy, for usually this is a two hour session.

OPERATIVE PROCEDURES

I am unquestionably skeptical of the value of appendicostomy, cecostomy and colostomy as curative measures. For the most part, the openings made into the bowel were used primarily for the purpose of irrigating the colon in the hope that some antiseptic solution would destroy invading organisms and thus effect a cure. In view of our present knowledge of the actual pathologic condition that exists, these three procedures are discarded as theoretically unsound and as actually being completely ineffectual. Complete removal of the diseased bowel is indicated and is essential to effect a "cure." Numerous operative procedures are employed; two, three or even four stages make for safety with debilitated patients. Ileostomy is usually the first stage. Through a McBurney incision the terminal part of the

ileum, if uninvolved, is divided 6 inches from the ileocecal valve; the proximal 3 inches is brought well out on the anterior abdominal wall. (The longer the segment of protruding ileum, the easier it is to manage the bag or dressing.) I decry the practice of exploring the abdomen at this stage, as well as of using a right rectus incision as a site for the ileostomy opening. To prevent loops of small bowel from adhering between the right lateral abdominal wall and the proximal segment of ileum, careful closure of this space should be done. Formerly the distal part of the divided ileum was closed in layers and dropped back. This practice has been abandoned; it is safer and more convenient for the second stage to bring the distal end out as a mucous fistula just to the left of the midline of the abdomen.

It has seemed to me that the acute fulminating, often rapidly fatal, form of short duration presents difficult problems. The desperately ill patient when first seen is not a good surgical risk, even for an ileostomy, an easily performed surgical maneuver. The clinicians, attempting to bring about a remission, often have waited too long. Even though the patient has not been sufficiently studied and rehabilitated, early diversion of the fecal stream by means of a double-barreled ileostomy might prove advantageous. If later the clinical evidence and roentgenograms indicate that the disease process has been arrested in the colon, the normal fecal flow might be resumed by crushing the spur, as has been suggested by Devine for the large intestine.

Four patients in our series had the acute form of the disease and were operated on, all having been ill for a period of not longer than three months without remissions; all died, two from massive hemorrhages, one from perforation of the sigmoid colon and one from inanition. All had an ileostomy. Ileostomy is accompanied by a high mortality usually because of the seriousness of the disease, the fact that surgical aid is solicited too late, and the rapid loss of fluids and chlorides. Ileostomy alone, with no further surgical intervention, has not infrequently resulted in prolonged freedom from symptoms. Some authorities have claimed positive cures. For example, Barney and Brust² reported a case in which a 19 year old youth with symptoms of rapidly fulminating colitis of short duration underwent a loop ileostomy immediately, with administration of Barger's autogenous vaccine. Three years later, sigmoidoscopic examination revealed an apparently normal sigmoid colon and rectum; the ileostomy opening was closed. In a recent communication to me Dr. Barney wrote that this patient was robust and overweight for his size and age; there were not more than three stools a day, and there were no pain and no signs of bleeding. I have performed ileostomy nineteen times as a preliminary step for total colectomy. In our series, a woman of 29 who had had the chronic continuous type for ten years had undergone ileostomy eight years before with improvement, yet because of hay fever each summer she suffered from diarrhea with bloody stools. Her disease was not sufficiently arrested, and recently, by removal of the entire colon, which was thoroughly diseased, we feel that her chance for cure was considerably enhanced.

If it has been determined that the lower, descending part of the sigmoid colon and the rectum are free from the disease, an end to side ileosigmoidostomy to divert completely the fecal current may wisely be carried out

2. Barney, C. O., and Brust, J. C. M.: New York State J. Med. 271: 1852-1853 (Nov. 1) 1937.

as a first stage procedure, with a partial or subtotal colectomy later, but let it be emphatically understood that such a procedure is applicable in less than 10 per cent of these cases. For that condition in which the terminal part of the ileum, the cecum and the ascending colon are involved, sometimes termed colo-ileitis, ileosigmoidostomy is suitable.

When the colon and rectum are involved only on the left side and the process has become sufficiently stationary, transverse colostomy is indicated. In the past, colostomies have been performed too near the diseased segment and the results, obviously, have proved unsatisfactory. Transverse colostomy produces an easily managed fecal stoma, which should be placed at least 12 inches proximal to the involved area. In the two instances in which I resorted to transverse colostomy, the disease had been restricted to the descending colon and rectum for more than three years. If patients suffering from this disease, which starts in the rectum and gradually invades the transverse and ascending colon, could be submitted to operation sooner, colostomy, which is assuredly preferable to ileostomy, would suffice.

The complete removal of the colon and rectum should be performed in three or four stages, the fourth stage reserved for the patients who are poor risks: (1) ileostomy (already discussed), (2) subtotal colectomy and (3) proctectomy.

We have performed subtotal colectomy eleven times, with one death. I draw attention to this fatality, for the patient, a boy aged 18, had presented a most unusual picture of the chronic continuous type of the disease for two years. A barium sulfate enema revealed that there existed an internal fistulous opening between the cecum, loops of terminal ileum and sigmoid colon. At operation, in an attempt to divide and close the fistulous tracts, leakage occurred. The patient died of peritonitis three days later. A long left paramedian incision affords ample exposure for removal of the entire colon and

mobilizes the hepatic flexure. Immediately after the ligation of the middle colic artery as the transverse colon is being freed, there is frequently a sudden fall in blood pressure; should this occur, immediate transfusion is advisable. Because of the extensive incision and the handling of the colon, heat is lost and a certain amount of so-called shock ensues if care is not taken to keep the intestine, particularly the small intestine, cov-

TABLE 3.—Analysis of Operative Deaths

Sex	Age	Form of Disease	Duration of Disease	Operation	Cause of Death
♂	20	Chronic with remissions	6 years	Ileostomy	5 days postoperative; technical error; gangrene of exteriorized loop; lobar pneumonia
♂	20	Acute fulminating	3 weeks	Ileostomy	9 days postoperative; massive hemorrhage
♂	56	Acute fulminating	7 weeks	Ileostomy	6 days postoperative; massive hemorrhage
♀	32	Chronic with remissions	3 years 6 months	Ileostomy	3 days postoperative; peritonitis; abundant cloudy fluid at time of ileostomy; desperately ill
♂	18	Chronic continuous	2 years	Subtotal colectomy	3 days postoperative; peritonitis due to soiling following division of internal fistulous tracts

ered with moist warm gauze pads. Hemostasis is meticulously attended to so that hematomas will not form between the leaves of the cut mesentery.

By far the most technically difficult part of this entire procedure is the division of the splenophrenocolic ligament, and it is through the long paramedian incision on the left side that this ligament is most easily identified and severed.

Thus far I have had but little difficulty in dividing the lower part of the sigmoid colon over a rubber guarded clamp as advised by Rankin or in turning the stump in with several layers of interrupted silk sutures. Should there be any question of a tight closure of the stump, it is advisable to bring it out as a mucous fistula, as is done in a first stage Lahey operation for cancer of the rectum.

Peritonealization of the raw surface where the colon has been removed we have thus far practiced. Cattell expressed the opinion that this is unnecessary. It does not prolong the operation to any appreciable extent and does minimize the opportunity for the formation of adhesions.

After subtotal colectomy the majority of the patients improve markedly, in fact to such an extent that the question naturally arises whether and when the rectum should be removed. In four instances we have been reluctant to resect the rectum because of a tremendous gain in weight and an apparently lessened activity in the remaining segment. When a bloody discharge continues to be extruded from the anal opening and there persists inflammatory involvement in the perirectal space, with or without the presence of fistulous openings, it seems preferable to perform proctectomy.

The third stage of the radical treatment is best carried out by the combined abdominoperineal resection in one stage, after the Miles technic. We are now accustomed to close the posterior wound tightly except for a small rubber tube drain near the tip of the coccyx. This practice has diminished considerably the period of convalescence and we feel, despite some opposition, that it is a justifiable procedure.

makes easier the division of the splenophrenocolic ligament. The omentum is detached from the transverse colon and pushed upward under the costal margins; this step simplifies the removal of the transverse colon and thus preserves the omentum for the purpose of covering raw areas and lessening the possibility of intestinal obstruction.

The terminal part of the ileum and the ascending, transverse and descending colon are removed. Care is taken to identify and protect the third portion of the duodenum and the right ureter as one exposes the retroperitoneal surface of the ascending colon and

A question often asked is how much time should intervene between the stages. From the stage of ileostomy to subtotal colectomy from three to eight months is usually allowed; from subtotal colectomy to resection of the rectum, four months seems sufficient.

Immediately after the close of each of these procedures, transfusion has unquestionably proved timely and beneficial.

Associated disorders, such as deficiency states, avitaminosis, rectovaginal and perirectal fistulas, delayed puberty, lack of skeletal growth, rickets, secondary anemia, tetany, and beriberi, have not simplified the surgical problems and added to the patients' safety; therefore every safeguard should be utilized for protection.

COMPLICATIONS

The commonest postoperative complication is peritonitis, frequently the result of perforation or soiling from technical mishaps during the process of colectomy. Persistent hemorrhage, pneumonia, sepsis, inanition, embolism, mechanical and paralytic ileus and thrombophlebitis are other hazards. The most striking feature of the surgical management of this disease is the enormous gain in weight, even after ileostomy alone

but more particularly after removal of the entire diseased colon. There has resulted an average gain of 42 pounds (19 Kg.) by the twenty-two patients who survived operation.

MORTALITY

Of a total of 257 patients studied, 158 were treated at the Roosevelt Hospital, with a gross mortality of 7 per cent. Six patients in this group died while under medical supervision, a mortality of 3.7 per cent. Twenty-seven patients were operated on; five of these died, giving an operative mortality of 18.5 per cent. Of the miscellaneous group (those not treated at the Roosevelt Hospital), which is presented for comparison, all have been followed by Dr. Mackie, many in the ulcerative colitis clinic, but were operated on in other institutions by other surgeons, ninety-nine in all, with a gross mortality rate of 14.1 per cent. Ten of this number died while under medical care, a mortality of 10.1 per cent. Thirteen were operated on, with a mortality rate of 30.8 per cent. This comparison is purposely drawn to emphasize the importance of a combined, carefully planned and meticulously followed approach between the physician and the surgeon who are directly in charge of the patients. These two groups, the Roosevelt Hospital group and the miscellaneous group, make a total, as has been stated, of 257 patients. The total mortality rate, i. e. medical and surgical combined, was 9.7 per cent. Sixteen died while under medical care, a mortality of 6.2 per cent. Of the forty patients operated on nine died, thus giving, for the two groups combined, a mortality rate of 22.5 per cent.

COMMENT AND CONCLUSIONS

Although twenty-seven patients operated on for this disease is not a large number, we feel that it is of sufficient size for the formulation of certain conclusions. If the condition of such desperately ill patients cannot be controlled completely by medical management, surgical intervention is essential; although they are bad risks, if the operative mortality rate is kept below 20 per cent, more patients should be given the opportunity for cure. A more detailed analysis of the five deaths among the twenty-seven patients operated on at the Roosevelt Hospital reveals that one patient, a man, desperately ill, died because of a technical error on my part. In an attempt to make ileostomy safer, I brought out on the anterior abdominal wall a loop of the terminal part of the ileum with the idea of opening it twenty-four or thirty-six hours later. Unfortunately, there was an embarrassment of the circulation with resulting gangrene and peritonitis. The second patient was a woman with a large distended abdomen filled with cloudy fluid, whose temperature was 102.5 F. and whose colon I believe had perforated before ileostomy was done. Two other patients were admitted to the hospital during an activated stage with massive hemorrhages and marked abdominal distention; ileostomy was attempted in the hope of staving off death. The fifth patient was the only one in the series to die after colectomy from peritonitis due to soiling at the time of disentanglement of internal fistulous tracts between the cecum, terminal ileum and sigmoid colon. Every effort is now being made to reduce the mortality by careful estimation of just how much surgical intervention the patient can tolerate, and I again emphasize that medical supervision should not cease at the time of operation.

Surgical intervention is indicated for perforations, repeated hemorrhages and strictures, for diffuse polyposis with or without malignant involvement and for conditions not relieved by medical management. Opinion varies concerning the indications for elective operation. As yet no definite criteria have been established for determining operability. Operative procedures must be based on and determined by the extent and situation of permanent damage to the colon. Pre-operative and postoperative medical supervision is essential to the successful outcome, for the patients are dehydrated, anemic, septic and often semicadaverous. It is difficult to determine whether to intervene surgically and when to do so with patients suffering from the acute fulminating, often rapidly fatal, form of this disease.

If the colon and rectum are involved only on the left side, transverse colostomy (in the healthy part of the bowel), with removal of the colon and rectum on the left, is justified. Should the colon be diseased on the right side and the rectum and sigmoid colon not involved, ileosigmoidostomy followed by subtotal colectomy is sufficient.

With extensive disease of the entire colon, removal of the affected bowel is accomplished in three or four stages. When the stage of intractability has been reached, elective operation, in spite of a mortality of about 20 per cent, offers more than a continuation of medical treatment.

Of 158 patients admitted to the Gray service, twenty-seven were operated on and five died, an operative mortality of 18.5 per cent. An average gain in weight of 42 pounds (19 Kg.) and marked clinical improvement justify surgical intervention, not for complications alone but in order to eradicate the disease.

On admission in January 1938 the patient was large and well nourished. When prostigmine was withheld for a few hours she showed marked general muscular weakness. She was unable to raise herself to a sitting position in bed. Her hand grip was good at first but fatigued almost completely in twenty seconds. The face was smooth and somewhat expressionless; there was weakness of all the facial muscles and those of the jaws and neck. There was ptosis of the eyelids. Her voice was somewhat nasal, enunciation was poor and there was fatigue from continued conversation. No muscular atrophy or fibrillary twitches were observed.

January 26 all drugs were withheld. Within twenty-four hours myasthenic symptoms were marked. Preliminary ergographic tracings were made (fig. 3) and 1 cc. of prostigmine solution (0.5 mg.) was injected intramuscularly. A typical marked improvement in muscle function resulted. The facial expression became less stiff and the patient could raise herself easily from bed. Within two or three hours after medication her weakness was as marked as before the injection.

Fig. 2 (case 1).—Response to intravenous injection of guanidine hydrochloride one hour after dose of prostigmine.

No further prostigmine was given. January 29, 10 mg. of guanidine hydrochloride per kilogram dissolved in physiologic solution of sodium chloride was injected intravenously. Within ten minutes the patient remarked on her feeling of increased strength, and ergographic tests indicated marked improvement. No undesirable symptoms were produced by this dose. The only sensation other than improved strength noted by the patient was a tingling of the lips and finger tips for a few minutes after the injection. Control injections of physiologic solution of sodium chloride gave entirely negative results. January 31 a slightly smaller dose of 6.6 mg. of guanidine hydrochloride per kilogram was given intravenously. There was the same prompt improvement in muscular strength, which had not entirely disappeared after eight hours (fig. 4). Again no undesirable symptoms were noted. February 2 the same dose of guanidine hydrochloride (6.6 mg. per kilogram) was administered by mouth. The response was only slightly slower than when the drug was given by vein. The same tingling sensation was noted and within thirty minutes there was a marked improvement in strength, which persisted about seven hours.

The problem from this point on was to adjust the doses of guanidine and the time of administration to get as well sustained and as even a level of improved function as possible. We now know that our progress in getting this patient on adequate treatment was unnecessarily slow. At the time, however, we were much more familiar with the intoxication produced by guanidine (discussed later in this paper) than with its therapeutic use and deemed it wiser to proceed carefully, with frequent chemical studies of blood and urine and measurements of blood pressure. The patient was kept in the hospital for a week on 10 mg. of guanidine per kilogram a day in three divided doses. The strength was fairly well maintained on this treatment. No undesirable symptoms were noted and the

concentration of guanidine in the blood in spite of medication was only 0.39 mg. per hundred cubic centimeters (an entirely normal figure) on the day of discharge.

The patient was sent home on 11 mg. of guanidine hydrochloride per kilogram daily and was seen each week for general check-up and chemical studies. On each visit the patient reported no undesirable symptoms and asked to have the drug increased. By March 1 the daily dose was 20 mg. per kilogram

and the patient was feeling considerably better than when on prostigmine. A sample of blood taken about two hours after the morning dose of guanidine showed only 0.41 mg. per hundred cubic centimeters. The blood pressure was 125 systolic, 88 diastolic. In April the dose was increased to 22 mg. per kilogram a day and in May to 28 mg. This total daily dose has been continued until the present time. On this treatment the patient is able to take complete care of herself and her room and do light work about the house. She enjoys picnics, rides and visits to her friends without extreme fatigue. Her knees still tire after a short walk but regain their strength after a short period of rest. There is no evidence of facial weakness at any time and no periods of complete "let down."

No atropine has been administered. Only an occasional single tablet of prostigmine has been taken before some especially strenuous activity. The highest level of guanidine in the blood noted at any time was 0.48 mg. per hundred cubic centimeters on one occasion two hours after she had taken a dose of 15 mg. per kilogram of the drug.

From the progressive gradual increase in dosage of guanidine in this case from the beginning of treatment to the present time one might conclude that tolerance was being acquired and that more and more of the drug was required. This was really not the case. The dose was not increased because a given amount of the drug had become less effective than previously but because we

Fig. 3 (case 2).—Response to 1 cc. of prostigmine given hypodermically.

learned with further experience that larger amounts could be given with safety and with additional improvement in muscular function.

Evidence that this patient is being maintained by guanidine and is not in a spontaneous remission is offered by the fact that on one occasion medication was withheld for a day. Her weakness returned and she collapsed in walking across the room and was unable

to rise from the floor without aid. As soon as a dose of guanidine was administered her strength promptly improved.

CASE 3.—H. W. C., a white woman aged 47, represents another case of myasthenia gravis of long standing. She came to Vanderbilt Hospital for observation and a trial of guanidine therapy.

On admission the patient was pale, fairly well developed and nourished and mentally alert and cooperative. Without medication there was marked generalized muscular weakness with rapid fatigue on repeated effort. The facial expression appeared stiff and "frozen." There was slight ptosis of the eyelids. Ocular movements were restricted and poorly sustained in all directions and convergence was poor. Enunciation was poor and the voice became almost inaudible after five minutes of speaking at a conversational pitch. The deep reflexes were physiologic but were soon exhausted by repeated stimulation.

On May 3 all medication was discontinued. May 5, 1 cc. of prostigmine solution was given intramuscularly. Within fifteen minutes the patient's voice was stronger, enunciation was more distinct and a marked improvement was observed in the muscles of the face and limbs. Ergographic records were obtained which gave further evidence of increased strength. Within two hours, however, the effect of medication was rapidly wearing off and somewhat later there was a period of depression during which the patient appeared weaker than before prostigmine was given.

Prostigmine was then discontinued entirely. May 6, 10 mg. of guanidine hydrochloride per kilogram was administered orally. Within thirty minutes there was marked improvement in muscular strength, which the ergographic records show persisted in a gradually decreasing degree for five hours (fig. 5).

Profiting by our experience in the previous case, we increased the administration of guanidine much more rapidly in this case, as shown in the accompanying table.

This amount of guanidine caused no undesirable symptoms, and muscular strength was maintained throughout the day at about the level attained shortly after a dose of prostigmine.

Since her return home she has continued to take daily from 25 to 30 mg. of guanidine hydrochloride per kilogram by mouth. She writes that she can take automobile rides and short walks without exhaustion. This summer she spent a week at the seashore during which time she enjoyed picnics, bathing (not swimming) in the ocean, sketching, painting and reading. She finds it necessary to lie down to rest only about an hour a day. Her eyes are normal (with glasses) and her voice and facial expression have become normal. Before the development of myasthenia gravis she had been a commercial artist. Now for the first time in several years she has been able to resume this type of work at home for a few hours a day without marked fatigue. Occasionally she takes one tablet of prostigmine before unusually strenuous activity. There have been no undesirable symptoms other than tingling of the fingers after a dose of guanidine and an occasional bad taste in the mouth from regurgitation of the drug.

CASE 5.—W. M. G., a white unmarried woman aged 32, admitted to Vanderbilt Hospital Aug. 1, 1938, complained chiefly of weakness.

On admission the patient was slender and poorly developed with marked generalized weakness. Except for a short time after a dose of prostigmine she was unable to move herself in bed or to make more than the feeblest attempts to move her hands and arms. She could not speak above a whisper, and enunciation was indistinct. Her eyelids drooped and she could not raise them; her facial muscles moved only slightly, and difficulty in swallowing caused the saliva to run from her mouth. There was rather marked deafness, especially on the left. Bone conduction was normal. She had a small external hemorrhoid. No cause was found for the slight tenderness and occasional

pain in the right lower quadrant. The remainder of the physical examination was essentially negative. The reflexes were present but somewhat hypo-active. The blood pressure was 110 systolic, 80 diastolic. The daily creatinine output in the urine was approximately 0.7 Gm. with occasional small amounts of creatine. The hemoglobin content was 12.2 Gm. per hundred cubic centimeters; the white blood cell count was 4,700. Nonprotein nitrogen was 34 mg. per hundred cubic centimeters. The Wassermann reaction was negative. Roentgenograms showed no evidence of thymic tumor.

Because of her inability to chew and swallow, the patient was considerably dehydrated and emaciated and weighed only 86 pounds (39 Kg.). After brief observation it was apparent that before any medication could be evaluated her fluid balance must be restored and her state of nutrition improved. The management of this case was therefore necessarily rather different from those previously studied. It was obviously impracticable at first to withhold prostigmine medication in order to study the patient's response to and tolerance for guanidine alone. During the first part of her stay in the hospital prostigmine medication

Fig. 4 (case 2).—Response to 6.6 mg. of guanidine hydrochloride per kilogram injected intravenously.

was continued, the drug being given orally when possible and hypodermically when necessary because of her inability to swallow. Guanidine, in varying doses ranging from 10 to 35 mg. per kilogram a day, was given as a supplement to prostigmine. On this regimen the patient showed considerable general

May 11	30	4

improvement. She could eat and drink without difficulty and was able to be up in a chair. She gained 6 pounds (2.7 Kg.).

September 5, more extensive studies for the evaluation of different types of medication were undertaken. Since the patient became so helpless without any medication, it seemed safer and more practicable to estimate the effectiveness of guanidine by using it as a supplement to a given constant level of prostigmine medication rather than to attempt to use guanidine alone. Accordingly, guanidine medication was withheld and the patient was given eight oral doses of 15 mg. of prostigmine daily.

This amount was chosen because previous experience had shown that it was just about the limit of her tolerance for prostigmine without the production of intestinal symptoms. On this medication alone the patient was considerably weaker than she had been on the previous combined treatments. After each dose of prostigmine there was temporary improvement in strength, but she complained of feeling nervous and of the marked "let down" as the effects of the drug wore off. She did not feel strong enough to be up in a chair. September 7, while this plan of treatment was continued, ergographic tracings were obtained at intervals of approximately three hours throughout the day (fig. 6). Strength was slight and poorly sustained at all times. September 8 the amount and time of administration of the doses of prostigmine were kept the same, but four oral doses of 250 mg. each of guanidine hydrochloride were given, one dose before each meal and one at 9 p. m. This total amount of guanidine represented a daily intake of approximately 25 mg. per kilogram. On this medication the patient felt stronger and wanted to get up in a chair, but in order to make a fair comparison

tigmine to ten doses a day and continuing seven doses of guanidine, there was still a period of rather marked weakness in the late afternoon. Since the hyperirritability produced in normal muscles by guanidine can be controlled by extra calcium,² it seemed possible that we might enhance the effect of guanidine on the muscular activity of this patient by giving extra potassium. Accordingly, starting September 11, 8 cc. of a 25 per cent solution of potassium citrate was given orally three times a day in addition to the drugs already in use. Apparently because of this addition, or at any rate coincident with it, the patient became considerably stronger and more active. Attendants in the ward who were not interested in the study remarked on the improvement, and the patient said that she felt better than she had for a long time. Ergographic tracings (fig. 8) taken at various times during the day and even at the usually poor hour of about 4:30 p. m. showed well sustained muscular strength. She began to walk about the ward more and could walk the length of a long hospital corridor and back with only moderate fatigue. During the last week of her stay in the hospital the administration of potassium citrate was continued and the amount of prostigmine was gradually reduced until only four doses were given. The guanidine hydrochloride was increased to eight doses of 250 mg. a day, making a total of about 45 mg. per kilogram—still without untoward symptoms and without any persistent elevation of guanidine in the blood.

September 22 the patient was discharged with directions to continue the combined medication of four doses of prostigmine, three doses of potassium citrate and eight doses of guanidine hydrochloride and to return in one month. She was seen in the outpatient clinic October 21, having come from her home, a distance of 100 miles, by bus. She reported that she had been feeling well and that she had been able to be up and about the house most of each day. She had gained 6 pounds. The blood pressure was normal. The level of guanidine in the blood was not significantly elevated in spite of the fact that the patient had already taken four doses of guanidine on the day she was seen.

COMMENT

The foregoing reports and ergographic records demonstrate that appropriate doses of guanidine hydrochloride given either alone or as a supplement to prostigmine induce a marked improvement in the functions of the muscles of persons with myasthenia gravis without the production of untoward symptoms. The drug may be administered either intravenously or orally and is about equally effective by these two routes. Solutions of guanidine hydrochloride are too irritating for subcutaneous or intramuscular use. Except in instances in which the patient is unable to swallow, the only practical method for continued use of the drug is by the oral route. We have used a 2 per cent solution in physiologic solution of sodium chloride for intravenous injection and have given the drug orally in gelatin capsules. We have found 10 mg. per kilogram a safe and adequate amount to give as a single dose to test the effectiveness of guanidine hydrochloride in a given individual. For continued medication the total daily dose, the times of administration of divided doses, the relative amounts of guanidine and prostigmine to be used must all be worked out in terms of the needs and tolerance of each individual patient. It has been our

Fig. 5 (case 3).—Response to 10 mg. of guanidine hydrochloride per kilogram by mouth.

of objective tests she was kept in bed. Ergographic tracings were again made at the same times as on the preceding day (fig. 7). Considerable improvement can be seen in each test as compared to the records obtained on prostigmine alone. There were, however, still periods in the day when strength was poorly sustained. The amount of guanidine was then increased to six and later to seven doses a day. The patient was allowed to be up in a chair and about the ward. No untoward symptoms developed and the guanidine levels of the blood determined on various occasions were always within normal limits. This treatment was continued for several days with some rearrangement of the divided doses in an attempt to eliminate periods of weakness.

During this time the patient was closely observed and frequent ergographic tests were carried out which cannot all be presented here. Although the improvement after the addition of guanidine was quite marked, we were not satisfied with the response in this case as compared to that elicited in cases 2 and 3. It appeared as if something were lacking in this patient which neither guanidine nor prostigmine could restore to the extent possible in some other patients. In spite of increasing the pros-

experience that a more evenly sustained level of improved function without a sensation of nervousness and without periods of sudden "let down" can be maintained on a regimen in which guanidine makes up a large part of the necessary medication. In one instance potassium citrate appeared to increase the effectiveness of prostigmine and guanidine.

Fig. 6 (case 5).—Tracings made at intervals of three hours during a day in which eight doses of prostigmine were given by mouth. At 4 p. m. the patient was too weak to attempt a test.

Much more work will have to be done before any final explanation can be offered either for the cause of the dysfunction in the myasthenic state or for the beneficial action of prostigmine and of guanidine in this condition. In our earlier paper we¹ outlined a working hypothesis which served as a basis for the therapeutic trial of guanidine in myasthenia gravis. Summarized briefly, the hypothesis rested on the following premises:

1. Acetylcholine plays an essential role in the normal transmission of nerve impulses to skeletal muscles.³

2. Physostigmine or the more commonly used prostigmine hinders the destruction of acetylcholine by an enzyme (choline esterase) which is normally present in the body.⁴

3. In myasthenia gravis there is some interference with the transmission of impulses across the myoneuronal junction.

4. An abnormality in the participation of acetylcholine in the transmission of motor impulses in myasthenia gravis is indicated by the effectiveness of prostigmine in temporarily restoring normal function in this disease.

5. There is no evidence that acetylcholine is absent or destroyed at an abnormally rapid rate in myasthenia gravis.⁵

6. In this disease, therefore, the muscles are less than normally responsive to a given concentration of acetylcholine.

7. Guanidine increases the sensitivity of normal muscles to the action of acetylcholine.⁶

Granted these premises, many of which are admittedly highly controversial, it appears inevitable that the administration of guanidine to persons with myasthenia gravis should enhance the effect of prostigmine or should by itself cause an improvement in the functions of muscles. Our therapeutic results are compatible with this working hypothesis.

Most of the work that has previously been reported on the pharmacologic action of guanidine is a study of the intoxication induced by the drug. Doses of from 150 to 200 mg. of guanidine hydrochloride per kilogram administered to experimental animals promptly cause an acute intoxication, which has been extensively studied.⁷ Severe guanidine intoxication is characterized by nervous hyperirritability, fibrillary tremors and convulsive contractions of muscles, salivation, vomiting, diarrhea, hypoglycemia and circulatory disturbances. The maintenance of a moderately increased concentration of guanidine in the blood of normal animals by the repeated administration of smaller doses or by excessive guanidine of endogenous origin has also been shown to cause a less acute but nevertheless serious and typical intoxication.⁸ The administration of calcium has been shown to control the nervous and con-

Fig. 7 (case 5).—Tracings made at intervals of three hours. Eight doses of prostigmine were given by mouth at the same time of day as on the day of tracings in figure 6 were made. In addition, four doses of 250 mg. of guanidine hydrochloride were given by mouth.

vulsive symptoms and to furnish some relief of the other manifestations of intoxication.⁹ Atropine, on the other hand, has been found to be more effective than calcium

in relieving the gastrointestinal symptoms, the circulatory disturbances and the changes in blood sugar induced by guanidine but to leave the nervous and muscular changes unaffected.¹⁰

In view of so much emphasis on the toxic potentialities of guanidine, its use as a therapeutic agent was naturally undertaken with considerable caution. From experiments with normal dogs we found that the daily administration of from 25 to 50 mg. of guanidine hydrochloride per kilogram for several days usually caused a moderate increase in the level of guanidine in the blood, accompanied by anorexia, occasional vomiting and hyperirritability. Similarly, when normal persons took daily doses of from 15 to 20 mg. per kilogram for two or three days they complained of nervousness, increased peristalsis and, in some instances, diarrhea. Chemical studies of blood showed that these symptoms appeared when the level of guanidine was maintained

We do not yet know the reason for the greater tolerance of patients with myasthenia gravis to guanidine. From the prolonged effect on the function of muscles, it does not appear to be due to a more rapid excretion of the drug. It seems rather that guanidine is more readily stored or transformed into some other compound by persons with this disease. The work of Wishart¹¹ suggests that at least part of ingested guanidine may be transformed to creatine in the muscles. However, until more experimental work is done it is useless to speculate in regard to the mechanism involved.

There is no evidence that guanidine is of value in any of the myopathies other than myasthenia gravis. There was no immediate improvement in function in a case of pseudohypertrophic muscular dystrophy or in several persons with vague complaints of muscular weakness to whom we have given test doses of guanidine. In ergographic studies made on normal persons before and after the administration of guanidine there is occasionally evidence of slightly better sustained muscle power after the drug is taken. This does not always occur, and in any case the effect is slight. It is difficult to say whether the difference is due entirely to psychic causes or whether the slight feeling of stimulation and nervousness which guanidine causes in some normal persons causes them unconsciously to make a greater exertion.

The best guide as to the level of continued guanidine intake that is safe for a given patient is afforded by determinations of guanidine in the blood. In our experience undesirable symptoms usually accompany any persistent significant hyperguanidinemia. Samples of blood for such studies should be drawn several hours after a dose of guanidine has been taken, as there can hardly fail to be a transient increase in the blood during the rapid absorption of a dose. The determination of guanidine in the blood is a rather complicated procedure and requires laboratory facilities and some chemical experience. We use the procedure described by Minot and Dodd.¹² The results obtained by different individuals with this colorimetric method are subject to enough variation so that it is important for each person to establish his own range of values for normal blood for comparison with figures obtained after treatment with guanidine has started. The absolute values obtained are of less importance than the degree of increase as compared to normal. In practice, however, the appearance of mild gastrointestinal symptoms (loss of appetite, nausea, increased peristalsis or diarrhea) serves nearly as well as chemical studies as an early warning that the tolerance is being exceeded and that medication should be reduced or temporarily withheld.

SUMMARY AND CONCLUSION

1. Treatment with guanidine hydrochloride has caused a marked and well sustained improvement in muscular function in five cases of myasthenia gravis without the presence of undesirable symptoms.
2. Compared to normal persons, patients with myasthenia gravis can tolerate larger doses of guanidine continued for an indefinite period without the production of hyperguanidinemia.
3. Gastrointestinal and other undesirable symptoms usually appear in both normal persons and those with myasthenia gravis when any significant elevation of guanidine is persistently maintained in the blood.

Fig. 8 (case 5).—Typical tracings obtained at intervals during a day on combined medication with prostigmine, guanidine and potassium citrate. Note the well sustained strength at usually "poor time" in late afternoon.

at from 0.5 to 0.6 mg. per hundred cubic centimeters, as compared to the normal level of from 0.35 to 0.45 mg.

When we started to treat persons with myasthenia gravis with guanidine we expected that daily doses of from 15 to 20 mg. per kilogram would increase the level of guanidine in the blood as they do in normal persons and that this hyperguanidinemia would probably cause undesirable symptoms. However, knowing that these symptoms could be controlled by atropine, we felt justified in testing the effect of guanidine on the function of muscles in patients with myasthenia gravis. As already stated in our case reports, we found that persons with myasthenia gravis can take considerably larger amounts of guanidine continuously over a long period of time than normal persons without causing any appreciable increase in the level of guanidine in the blood. A marked improvement in the function of muscles in this disease results without the production of persistent hyperguanidinemia and without symptoms of intoxication.

12. Minot, Ann S., and Dodd, Katharine: Guanidine Intoxication, a Complicating Factor in Certain Clinical Conditions in Children, *Am. J. Dis. Child.* 46: 522 (Sept.) 1933.

4. While these symptoms can be relieved by atropine, they should serve as a warning that the administration of guanidine should be temporarily reduced or withheld.

5. Treatment with guanidine may be combined with medication with prostigmine. In our experience, however, a more evenly sustained improvement in muscular function has been obtained when guanidine makes up a large part of the necessary medication.

6. In one case the administration of potassium citrate appeared to increase the effectiveness of treatment with guanidine and prostigmine.

7. More work is necessary before any adequate explanation can be given of the effectiveness of guanidine in restoring function to muscles in myasthenia gravis.

THE DIAGNOSIS AND TREATMENT OF MYASTHENIA GRAVIS

WITH SPECIAL REFERENCE TO THE USE OF PROSTIGMINE

HENRY R. VIETS, M.D.

AND

ROBERT S. SCHWAB, M.D.
BOSTON

The syndrome of myasthenia gravis was first suggested by Thomas Willis¹ in 1672, but the disease was not clearly delineated until the reports of Erb² in 1878, Goldflam³ in 1893 and Jolly⁴ in 1895. The first patient to enter the wards of the Massachusetts General Hospital with myasthenia gravis was admitted in 1905. In the period between 1905 and 1934 inclusive thirty-one patients received this diagnosis in the wards (fig. 1) and possibly a few more in the outpatient department. The disease was thus rare, only one patient a year, on the average, being seen in a moderately large general hospital. Seven of the thirty-one are known to have died either within a few weeks in the hospital or within a year at home. The disease was rapidly fatal, probably even more so since our follow-up records were not complete, than our ratio of 7 in 31 would indicate. The average age at death in this early series was slightly over 35 years. During this period, moreover, treatment was nearly unavailing. After 1930, ephedrine sulfate and aminoacetic acid were used by us with moderate success, in accordance with the experiences of Edgeworth⁵ and of Boothby.⁶

A new era in the history of myasthenia gravis was begun by Walker,⁷ who treated her patients with phy-

sostigmine and later with prostigmine. Her work was soon confirmed by Pritchard⁸ and by Pritchard and Walker.⁹ The rapid response to prostigmine given by injection led to its use as a diagnostic measure by Viets and Schwab.¹⁰ Harvey and Whitehill¹¹ and Gammon and Scheie.¹²

The oral administration of prostigmine, first proposed by Everts,¹³ was extensively elaborated by Viets, Mitchell, and Schwab¹⁴ in 1937.

Our knowledge both of the disease and of its response to prostigmine has greatly increased in the last three years, as indicated by the reports of Boothby¹⁵ and of Kennedy and Moersch.¹⁶

EXPERIENCES AT THE MASSACHUSETTS GENERAL HOSPITAL FROM 1905 TO 1939

Seventy cases of myasthenia gravis have been observed between 1905 and 1939. Since treatment with prostigmine was begun in 1935,^{10a} the myasthenia gravis clinic has rapidly expanded, forty-four cases being studied in the five year period from 1935 to 1939 (fig. 1). The highest incidence occurs in the second and in the fifth decade of life, but the incidence is fairly steady between the ages of 10 and 70 (fig. 2). The preponderance of patients in the early years of life,¹⁶ usually stressed in previous reviews of the disease, has not been shown by our figures. In general the patients have shown a similar set of symptoms throughout the years. The presenting symptom in

Fig. 1.—Incidence of myasthenia gravis at the Massachusetts General Hospital from 1905 to 1939; total number of cases, seventy. The asterisk indicates the introduction of prostigmine.

twenty-nine of seventy cases was ptosis; general weakness, dysphagia and diplopia were found in eleven, eleven and eight cases, respectively (fig. 3).

The prostigmine used was furnished partly by Hoffmann-LaRoche, Inc. From the Myasthenia Gravis Clinic, Massachusetts General Hospital and the Department of Neurology, Harvard Medical School. Paper number five.

The diagnosis of myasthenia gravis is usually not difficult from the history and the clinical examination. The Jolly reactions were found to be of moderate assistance in diagnosis but proved to be not so valuable as the ergographic examination, especially in cases of general muscular weakness. In the ergograph test the

Fig. 2.—Age at onset of symptoms in the seventy cases.

muscles are exhausted by repeated pressure on a bulb, an observation easily recorded on a moving drum (fig. 4). Similar curves may be recorded in an electromyogram, as reported by Lindsley,¹⁷ who examined some

Positive Test: Myasthenia Gravis		

of our patients. The most efficient test for the disease, particularly useful for patients with few symptoms, is the "prostigmine test," as reported in previous communications.¹⁰ The results are quickly tabulated (table 1). By careful evaluation of the results, diseases such as psychoneurosis and numerous neurologic conditions giving rise to ptosis, diplopia, dysphagia, dysarthria and general muscular weakness are eliminated. The test has proved in our hands to be a valuable diagnostic procedure. In addition, for patients with dysphagia, fluoroscopic examination has been helpful (fig. 5), the barium sulfate being observed both before and after the injection of prostigmine. Chemical studies have not been helpful in diagnosis, as was the case in Boothby's

long series.¹⁵ We have been unable to associate myasthenia gravis with enlargement of the thymus gland. All roentgenologic studies failed to reveal such enlargement, and in two cases air injected into the mediastinal cavity failed to show the gland in the roentgenograms. This was surprising in view of the report of Norris,¹⁸ who observed hyperplasia of the thymus in 50 per cent of his four patients examined post mortem and found an equal incidence in the literature.

THE TREATMENT OF MYASTHENIA GRAVIS
SINCE 1935

Treatment with intramuscular injection of prostigmine methylsulfate was begun in 1935, but after the report of Everts¹³ prostigmine bromide for oral use

without serious results in severely affected patients. More important than the size of the dose, however, is the spacing of the drug throughout the twenty-four hour period. We found useful a prescription form on which the hours of the day were numbered, so that the dose could be accurately regulated. The schedule is

Fig. 4.—Ergograms in a case of myasthenia gravis taken before and after the use of prostigmine was begun.

given to the patient, a duplicate being retained. Typical schedules show a wide variety of spacing and dosage, as well as the other drugs used with prostigmine (table 2).

Regulation of the dosage was not by any means easy, and two groups of patients presented particular difficulties. The first group consisted of patients with severe involvement, with dysphagia and dysarthria as the presenting symptoms. For these large doses of the drug were necessary, from ten to twenty pills of 15 mg. each daily, in order to obtain a maximum effect. The patients in the other group, a smaller one, were sensitive to prostigmine and required small doses, 7.5 mg., spaced widely throughout the day. Once the dosage was regulated so that the patient was getting the maximum effect throughout the day and night, no change was necessary for months and no increased tolerance or disagreeable

effects from accumulation of the drugs was observed. The regulation of the dosage required some weeks or even months, and for this reason our patients were seen at weekly intervals. After the patient was satisfactorily adjusted to his medicine, we interviewed him once every four to eight weeks.

Because of the high cost of prostigmine, we endeavored to find a more potent form for oral administration. About ten times as much for oral as for intramuscular administration is required to give the desired effect. We tried enteric coated prostigmine, prostigmine eye drops, suppositories of prostigmine and inhalations of prostigmine powder (table 3). Enteric coated tablets do not materially affect the value of prostigmine. The drug may be given successfully by

suppository but not by eye drops or powder inhalations. Oral and parenteral administration are therefore the methods of choice.

Various drugs may be used to increase the effects of prostigmine. Many were tried in constantly changing doses and amounts (table 4). The most useful was ephedrine sulfate, a drug having by itself a definite effect on myasthenia gravis. Ephedrine increased the effect of the prostigmine in forty-one of forty-three cases and failed in only two. Aminoacetic acid, contrary to our expectations, from Boothby's reports,¹⁵ proved to be of no value in seventeen cases. As much as 45 Gm. a day in divided doses, a larger amount than Boothby recommended, was given.

After the work of Minot,²⁰ twenty-five of our patients received guanidine orally, alone or with prostigmine, a variety of guanidine salts being used. Guanidine carbonate was the most satisfactory compound, but the hydrochloride was about as effective. Guanidine increased the effect of prostigmine in eight of twenty-

Fig. 5.—Fluoroscopic study with barium sulfate in a case of myasthenia gravis with marked dysphagia. A was taken before and B after the use of prostigmine was begun.

five cases. In four the results were good. Seventeen other patients, however, failed to respond to guanidine. Potassium chloride in doses of 20 Gm. a day, given in a 25 per cent solution, was effective in reducing the intake of prostigmine in cases of severe involvement.

20. Minot, A. S.; Dodd, Katharine, and Riven, S. S.: The Response of the Myasthenic State to Guanidine Hydrochloride, *Science* 87: 348-350 (April 15) 1938.

Of fifteen patients using potassium chloride with prostigmine, there was a decided benefit in ten. Vitamin and endocrine treatments were not helpful. Three of our patients, however, were improved during pregnancy; one was worse.

RESULTS OF THE ORAL THERAPY WITH PROSTIGMINE

Forty-four patients in our clinic have now been taking prostigmine orally for from a few months to two and one-half years (fig. 6). Thirty-one have taken the drug more than one year and nine more than two years. During this period (1935-1939) there have been five deaths, four of patients over 50 years of age and one of a patient aged 27 (table 5). The mortality figures indicate that of eighteen of our patients over 50 years of age, 22 per cent have died. One of the twenty-six patients under 50 (4 per cent) died of the disease. In the older group, two died of causes incident to age and the other two failed to take prostigmine consistently. The younger patient died of myasthenia gravis in spite

Fig. 6.—Duration of treatment in forty-four cases of myasthenia gravis, 1935 to 1939.

of adequate treatment. Her pathologic examination will form the subject of a later communication. No gross thymic tumor was found.

Remissions have occurred in seven cases, so that prostigmine is no longer required. This is a somewhat larger percentage than might be expected in the natural course of the disease in forty-four patients with various

types of myasthenia gravis. Five patients, moreover, have been able to reduce their intake of prostigmine.

CONCLUSION

The results of the treatment of forty-four patients with myasthenia gravis in a period of two and one-half years indicate that prostigmine bromide taken by mouth and supplemented with ephedrine sulfate, potassium chloride and occasionally guanidine is the most efficient form of treatment for myasthenia gravis now available. Of the forty-four patients, five have died and seven have shown full remissions.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. MINOT, DODD AND RIVEN AND
DRs. VIETS AND SCHWAB

DR. J. C. MCKINLEY, Minneapolis: Myasthenia gravis is a disease which can now be removed from the category of hopelessness and almost invariable fatality to that of reasonable well-being and markedly improved life expectancy, thanks to the group of investigators to which the previous speakers belong. That the problem is not yet completely solved is indicated, however, by deaths in the series of Drs. Viets and Schwab in spite of treatment which they considered optimal. Then too, in both papers, reference has been made to such puzzling observations as the variability in response to prostigmine and guanidine and the occurrence of true remissions in a certain proportion of myasthenic patients—with or without therapy.—Presumably insight into questions of this sort will be gained as our understanding of the metabolic mechanisms of muscle tissue improves.

The recent advances in the therapy of myasthenia are a stimulus to thinking and, therefore, to clinical, physiologic and chemical research. To my mind this is a by-product of major importance. Drs. Viets and Schwab have referred to the occurrence of remissions in seven of their forty-four patients under prostigmine therapy. They state that this represents a somewhat larger percentage of remissions than might be expected in the natural course of the disease. One cannot take issue with this as a statement of raw fact, but in reading it unmodified one can scarcely avoid the inference that prostigmine was somehow responsible for producing some of the remissions in treated cases. That is only my reaction. Possibly such an inference is actually correct. With no desire to be hypercritical of the splendid work of the writers, I feel that on this point they are vulnerable to criticism on statistical grounds. It is apparent that a shift of one or two, or possibly three, cases into or out of the group of the remissions could easily occur by chance in another series in the process of random sampling. This would markedly alter the percentage of remissions. The reference to an increase in the remission rate under treatment is thus not valid unless the differences can be shown to have statistical significance.

DR. S. S. RIVEN, Nashville, Tenn.: My association with Dr. Minot and Dr. Dodd is that of a clinician, and I have been following these patients. We do not know yet how guanidine brings about the prompt, temporary improvement in myasthenia. We are not certain as to the mechanisms involved in the action of prostigmine. The two therapeutic agents may or may not work through the same mechanism. Certainly with respect to their action on cholinesterase activity the two drugs are quite dissimilar. Concentrations of prostigmine as low as one part per million completely inhibit esterase activity, while guanidine in amounts as great as one part per hundred, a level hundreds of times as high as can be maintained in vivo, has no effect whatever on the activity of this enzyme. We do not yet understand the basis of the greatly increased tolerance for guanidine on the part of myasthenic patients. We have shown experimentally that they do not merely excrete it faster than normal individuals, nor does its administration cause an increased excretion of either creatine or glycoylamine in the urine. Further than that we cannot say at present. The fact that calcium salts were shown in the earlier work of Dr. Minot to control the increased muscle tone and tremors induced by toxic amounts of guanidine, together with the observation that occasionally potassium enhances the effect of guanidine in myasthenia, suggests that changes in salt equilibrium may be of fundamental importance. There are one or two clinical facts that I should like to emphasize. Not a single patient in our series showed any spontaneous remission. A dose of guanidine which produces a toxic effect in a normal individual causes no undesirable symptoms in patients with myasthenia gravis. It seems that patients with myasthenia gravis respond to guanidine as pernicious anemia patients respond to liver.

DR. ANN S. MINOT, Nashville, Tenn.: I think that our experiences and Dr. Schwab's experiences indicate that guanidine probably has a place in the symptomatic treatment of myasthenia gravis. I do not think it is a cure of the underlying condition. Perhaps the greatest interest from the physiologic point of view is that each new drug that brings about a response in this disease gives us a new tool, a new method of approach to a condition about the cause of which we know nothing. If we can get several angles of approach, I hope that perhaps from this work we may get a better understanding of the condition itself and of the essential features of successful therapy.

DR. HENRY R. VIETS, Boston: I think that neither of these papers can be considered as final in any sense of the word. They are merely progress reports. We knew little about myasthenia gravis even five years ago, although the disease had been adequately described. In the last five years we have had the opportunity to observe closely forty-four cases of myasthenia gravis. We are learning something about the disease and the methods of controlling it. I think we have no statistics that are really of any value in regard to remissions. Our statement that seven of our patients out of forty-four were now in remission appears to be a figure that, when compared with the literature, is larger than has been noted before. We have no real basis of comparison, however, because of the thirty patients

who were observed at the Massachusetts General Hospital from 1905 to 1935 seven died in the hospital or almost immediately after leaving it. The evidence is that probably a great many of the others died within a year or two. A fair conclusion to draw with regard to remissions is that we now have drugs, such as guanidine, prostigmine and ephedrine, that carry patients through serious attacks of myasthenia gravis, even preventing death, and, therefore, permit them to recover to a state where remission is possible. If that is so, we are saving a large number of patients who previously would have succumbed to the disease. Certainly, of the forty-four patients whom we have observed, at least one third and perhaps one half would have died within a year or two after they were first seen, without the beneficial effect of ephedrine, guanidine and prostigmine.

HISTORICAL NOTES ON CORONARY OCCLUSION: FROM HEBERDEN TO OSLER

FRANK BILLINGS LECTURE

GEORGE DOCK, M.D.

PASADENA, CALIF.

In the Section on Practice of Medicine I have had the honor of acting as secretary, chairman and orator, no doubt by the active intervention of Frank Billings; but the Frank Billings Lectureship is so special a distinction that I cannot adequately express my appreciation of the honor. I enjoyed Frank Billings's friendship for a long time and realized his rare personality, his unusual genius as practitioner, consultant, teacher and leader of far reaching influence, and one of the most stimulating factors in the growth of the scientific element in the American Medical Association.

In selecting a topic worthy of the occasion I was moved by long-standing interest in the subject and also by recalling the part played by many of my friends and Billings's pupils and associates in the investigation of the physiology and pathology of the coronary arteries, and especially by the long continued and successful work of James B. Herrick. Three years ago George Blumer gave a model study of one form of coronary disease. As new material accumulates we tend to forget the early history of a subject, and as there are still lessons to be learned from that I decided to give a short essay on some of the chief incidents of coronary study from the time of Heberden to that of Osler.

TERMINOLOGY

The coronary arteries were looked at before the time of Heberden; alterations were described and some symptoms noted, but the former remained as anatomic curiosities and all were buried until more inquisitive times. By giving to a group of symptoms a euphonious name that has survived until now, William Heberden (1768) opened a new chapter in nosography, and so the name deserves a brief consideration. "Angina" as a technical term came down from classic times, and for almost two centuries before Heberden it was used in England to designate cases of quinsy or sore throat in which a feeling of strangling and anxiety entered. "Chest pang" was therefore an apt name for the syndrome that arrested Heberden's attention. No theory was suggested, and the seat was indicated only in a general way. Those who use the Oxford Dictionary may think I err in giving Heberden priority, because

that great storehouse of words gives a reference to "1744, Walls, on the Angina pectoris." I was unable to find the reference in the *Philosophical Transactions* and wrote to the Clarendon Press for information. A prompt and courteous reply stated that the date 1744 "rests on no foundation" but that in the "Medical Tracts of John Wall," published in 1780, is a letter to Dr. Heberden "On the Angina Pectoris." Angina was used in Germany at the same early period for cases of sore throat or croup, probably including diphtheria, and continued to the present time, extended with the recognition of leukopenic sore throat. Soon after Heberden's first article Germans translated his name for the disease as "brustbraeune," "browny" being an old technical term for the common anginas, and although it was promptly criticized by informed writers it persisted for many years. Objections to Heberden's term brought forth many substitutes, most of which did not long survive and need not be recalled. Parry proposed syncope anginosa, although syncope was not a frequent symptom or when it seemed present was sometimes the passage into death. "Stenocardia," proposed by Brera (1810), was objected to as arising from an erroneous conception of the nature of the disease but has been used down to the present time, especially in Germany, and is often useful as an adjective.

The coronary arteries entered medical thought and literature with the belief held by a brilliant group of English medical men, Edward Jenner, John Hunter, John Fothergill and Caleb Hillier Parry, that those vessels were closely associated with angina pectoris, and their view was quickly adopted by some of the leading physicians of Europe, especially Kreysig, whose three volume work on Diseases of the Heart appeared from 1814 to 1817, and by Brera (1810) and Testa (1810) in Italy. In 1809 Allen Burns published "Observations on Some of the Most Frequent and Important Diseases of the Heart." In the chapter entitled "Observations on Disease of the Coronary Arteries, and on Syncope Anginosa," he agreed with Parry as to the importance of cardiac ischemia but did not attempt to settle the question whether in angina the heart is in a state resembling paralysis or in a spasmodic contraction.

The attitude of early French authorities has troubled later writers. Corvisart did not make a definite statement about angina pectoris or the coronary arteries in that condition. But the work of Corvisart on the heart is not a textbook or monograph on modern lines. It is a collection of lectures entitled "Essay on the Diseases and Organic Lesions of the Heart and Great Vessels," taken from Corvisart's clinical lectures and prepared by an editor, C. E. Horeau, first printed in 1806 and republished several times later. In the chapter on Rupture of the Heart a number of cases are cited, including some that may have been due to infarcts in angina subjects, but without sufficient detail. Incidentally, the "aneurysm of the heart" of Corvisart was not what we now call aneurysm or partial aneurysm but dilatation. The heterodox views of Laënnec include two classes of ideas, one a matter of classification, the other that of clinical observation. As to the first, he classified angina pectoris as a nervous disease. At that time nervous diseases were even less understood than were diseases of the heart. Laënnec, even as an undergraduate, was a pioneer in pathologic anatomy, and he wrote the chapters on that subject in the "Dictionnaire des sciences médicales," just beginning its series of

sixty volumes. In volume 2 (1812) he divided all diseases into two classes. "First, those accompanied by an obvious lesion in one or many organs, hence called, for some years, organic diseases; second, those which show no constant lesion in any part of the body from which their origin could be derived. These are commonly called nervous diseases." He continued: "If one is called to a patient with an affection of the thorax in which dyspnea is the principal symptom and where one finds no signs indicating pulmonic phthisis, a disease of the heart, an aneurysm of a great vessel, or any other organic affection of the parts contained in the thorax, one can conclude that the disease is nervous." In volume 2 of the *Traité de l'auscultation médiate*, 1826, page 744, he designated nervous disorders of the heart and great vessels, including neuralgia of the heart, nervous palpitation, spasm of the heart with bellows murmur and fremitus, nervous disorders of the arteries, spasm of the arteries with murmur and fremitus. The section on Heberden's angina pectoris begins on page 745 under the heading Neuralgias of the Heart. He was familiar with the symptoms, especially of the mild forms, but we are surprised when he tells us that he opened many bodies in angina cases without finding the coronary arteries ossified, the term then used for arteries stiffened by sclerosis. But we cannot understand any more than when under treatment he tells us of the good results he had from placing two magnetized steel plates over the front and back of the patient.

APPLICATION OF PHYSICAL DIAGNOSTIC METHODS

The real study of heart disease began only after percussion had been applied in diagnosis and Laënnec had shown the scope of auscultation. When that was done a period of active application of physical diagnostic methods began and the steady round of discoveries in the diagnosis and pathology of valvular disease may have diverted attention from the less objective signs of angina pectoris. At all events, interest in the coronary arteries waned and interpretations of angina as a nervous disease began to multiply, although the real study of diseases of the nervous system had hardly passed the stage it was in while Laënnec was alive. Some of the arguments against the coronary theory of angina pectoris seem very weak now. One of the most popular was that coronary disease was often present without angina, and this was used with such a feeling of finality that it might serve as a warning in many clinical puzzles. Often the coronary arteries were not examined or if so in a very casual manner, and the statements as to ossification do not describe the real condition of the wall or the surface of the intima over a thickening. We know that in some cases there were rough spots on the intima where platelets might settle and be followed by fibrin formation, with danger of thrombosis or embolism at some time later, in one of many varieties of size and location. Also in many such bodies the subjects had missed the danger of a coronary accident by dying early, and if they had lived even a short time more might have had an attack of angina, an infarction with recovery or a rupture of the ventricle. From time to time a more thoughtful observer published a suggestive report, but with no impression on the opinion of the time.

THE PERIOD OF EXPERIMENTATION

The next period in the development of the study of coronary disease, that of experiment, began with a suggestion by Dr. Marshall Hall, best known for the

discovery of reflex action but recognized in his lifetime as a wise practitioner and a keen and versatile physiologist. In the Gulstonian Lecture in 1842 he took as his subject "The Mutual Relations Between Anatomy, Physiology, Pathology, and Therapeutics, and the Practice of Medicine." One section was headed "The Coronary Circulation; Sudden Death." Referring to Bichat's "tripod of life," he stressed the importance of sudden death due to arrested coronary circulation. He said that ossification of the coronary arteries or "a substance resembling cartilage in the walls" of those vessels was the common cause of syncope and death. He had proposed to himself to test the problem by arresting the circulation by ligation or by the injection of solid substances into the coronary arteries, and he gave details of the methods to be used.

In the same year the young surgeon famous later as Sir John Eric Erichsen reported some experiments. In dogs and rabbits he passed ligatures by curved needles around the coronary arteries and found that he could cause a speedy cessation of the heart's action. This work was referred to by many later writers, but no control was attempted for another twenty years. In 1862 Prof. P. L. Panum, then in Kiel and recognized as a brilliant physiologist, published "Experimentelle Beiträge zur Lehre von der Embolie," an extensive study based on Virchow's epoch-making investigation on embolism. Panum had witnessed some of Virchow's experiments and he began his work in the hope of enlarging discoveries already made. He thought his observations gave reason for doubting Virchow's belief that lack of arterial blood in the coronary arteries was a cause of death and that "angina cordis seu pectoris" could be the result of embolism of those vessels, but he did not deny that sudden death might follow obstruction of the coronary artery. He knew of Erichsen's experiments only through Virchow's reference to them and was uncertain how early the heart stopped or whether other circumstances altered the results of the operation. He wished to make some ligations but thought it impossible to do so on the moving hearts of live animals. It was then that he spread the case of Thorwaldsen beyond the Danish language. The celebrated sculptor died suddenly in the theater and, post mortem, atheroma and calcification were found and an atheromatous abscess in the anterior coronary artery, which had burst into the lumen, filling the latter with its soft contents. Dr. Fenger, who had assisted at the autopsy, wrote to Panum saying that he thought the interruption of the circulation through the coronary artery had lamed the muscle and so led to death. Panum commented: "The probability cannot be denied, but the facts are not convincing. For we do not know when the atheroma burst, immediately or hours before the death struggle. Also, there are no data on the histological condition of the muscle fibers. If they were fatty degenerated, as is not improbable, the cardiac paralysis might be due to the same cause, admittedly unknown, that so frequently leads to death in cases of fatty heart without participation of the coronary arteries. Finally, no one can tell the behavior of the heart during the death struggle, which might have lasted minutes rather than seconds." One must admire Panum's skepticism. He clearly recognized the complexity of experiments on coronary arteries but did not realize the meager knowledge of cardiac physiology and pathology at the time, and his experimental embol-

isms did little to enlarge them. It is interesting to know that he died of ruptured left ventricle at the age of 65.

The next experimenter was another prominent physiologist, Albert von Bezold, professor in Würzburg. In the course of a long series of studies on the heart and circulation (1863-1867) he examined changes in the heart beat after compression of the coronary arteries in some twenty rabbits. In most cases the operation had no immediate effect on the pulse rate; if any, it became slow rather than fast. In short, von Bezold did not agree with Virchow that obstruction of the coronary artery could cause fatal asphyxia. In all the early experiments associated phenomena were over-emphasized, and discussions about them diverted attention from the main topic.

Dr. B. Samuelson of Königsberg (1881) made experiments suggested by the case of a man who had focal brain symptoms (syphilitic), recovered after treatment but then had "asthmatic attacks" attributed to fatty heart largely because he was obese. After five years of freedom from symptoms he went into collapse, with a pulse rate of 35, and died in five hours. Autopsy revealed sclerotic coronary arteries, the lumen almost obliterated and no fatty degeneration. Samuelson made experiments after von Bezold's method, with the assistance of the physiologist Professor Gruenhagen. Even with complete occlusion he got no immediate cessation of heart action, and death followed only long continued or repeated obstruction. Following obstruction he found, among other changes, enormous swelling of the left auricle, relieved by loosening the ligature but never recovering completely. He thought that the mechanism after artificial occlusion must be the same as in angina pectoris; that the swelling explained the substernal pain, while the altered heart action, weak pulse, pallor and cold extremities went far to account for the anxiety. He admitted that sclerosis of the coronary arteries did not fully explain angina pectoris and agreed with Parry and Stokes that the symptoms of the latter were due to transitory weakness in a heart already weak. Divergent results in animal experiments he explained by differences in strength.

The next important experiments were made by Julius Cohnheim and Anton von Schulthess-Rechberg (1881). Cohnheim had an unusually sound physiologic point of view and he had practiced in Carl Ludwig's laboratory the methods used in work on the circulation. Instrumental assistance was carried out more fully than in previous attempts. Cohnheim premised by stating that pathologists had shown that an examination of the heart was incomplete unless the coronary arteries were minutely scrutinized and that since that had been accepted many diseases of the heart formerly called idiopathic had been shown to be the results of coronary disease, especially "fatty degeneration," "fibroid myocarditis" and aneurysmal dilatation of the left ventricle. Many good observers considered neuralgia of the heart, angina pectoris and sudden death as coronary effects, but as the matter was still unsettled he undertook the experiments described. He selected dogs on account of the superficial course of the coronary vessels in those animals, with branches much like those in man, and rather large dogs. He convinced himself that the arteries were end arteries and so lent themselves to obstruction of definite areas, although he did find one anastomosis in a large number of dogs. He realized the differences between human arteries with chronic

thickening and those of lower animals with artificial occlusions, and he knew that in human subjects circulation may proceed even with a certain reduction of lumen and that, if sudden obstruction occurred, something new must have happened. He recalled that in the brain acute softening takes place in areas where the arteries are thickened and calcified. A minimum of blood suffices for function to continue, but unusual exertion or emotional strain makes demands too great for the supply. It is not necessary to describe the details of his experiments. There was no effect in less than thirty or forty seconds after ligation. Then the pulse became intermittent, then frequent, followed by slowing and a sudden arrest of both ventricles in about 105 seconds. The auricles continued to beat, but feebly, and the ventricles began a "wallowing" or fluttering motion. Swelling of the auricles was transitory, if it did occur. Contractions did not return after ligatures were removed. Cohnheim thought he could exclude vagus participation. He discussed the possibility of a heart poison, interesting now but chimerical at that time. He also gave a comparison of experimental and clinical conditions following occlusion.

Another experimental study was made by an accomplished young American physiologist, W. T. Porter (1892-1896). His results did not differ essentially from those of Cohnheim, but he clarified the end artery problem, showing that "not the absence but the character of the anastomosis is the basis of the present teaching in pathology" and that "the idea of terminal arteries is physiological, not anatomical."

Soon after Roentgen's discovery a pupil of Porter, Dr. Walter Baumgarten of St. Louis (1899), made a contribution to the application of x-rays to the coronary arteries.

About the same time as Porter's early work, Dr. Rudolf Kolster (1893) of Helsingfors reported the results of a series of experiments in which small branches of the left coronary artery were ligated and the occluded areas examined at intervals of from one day to more than a year. The results agreed to a striking degree with observations after accidental infarction.

WORK OF THE PATHOLOGISTS

The later experimental work confirmed the beliefs of Jenner, Parry and their followers and brought the subject of coronary obstruction definitely into pathology. Before taking up the work of pathologists it will be useful to consider the views of some great clinicians of the nineteenth century. Stokes (1855) said: "We may conclude that the special group of symptoms described as angina pectoris . . . is but the occurrence, in a defined manner, of some of the symptoms connected with a weakened heart. Obstruction of the coronary arteries may or may not be present and is probably not infrequent, but as a cause of angina its action is remote and its existence unnecessary. It is only by causing atrophy with fatty degeneration, as Dr. Quain has shown, that it appears remotely to produce angina." He compared the heart in angina to an intestinal tube with ileus and also suggested over-distention of collateral vessels as an explanation of the pain. He had never seen the severe form of angina described by Latham or the purely nervous cases of Laënnec. He thought that cases most often called angina might be more properly designated cardiac asthma, and he suggested useful clinical and anatomic methods for the better study of cases. Trousseau

(1873) called angina pectoris "this singular neuralgia" but was aware of the variety of lesions found with it. The English translation of Ziemssen's *Encyclopedia*, nineteen volumes, 1874-1879, was a great stimulus to medical thought in the United States. The Index of the Heart volume does not contain the words angina pectoris, stenocardia or coronary artery, but the latter is mentioned (vol. VI) as the cause of rupture of the heart. Angina pectoris is treated under Diseases of the Nervous System in volume XIV, page 31. Senac, Corvisart and other early writers are quoted to controvert the coronary theory, and angina pectoris is described as a definite disturbance of the innervation of the heart. Austin Flint, whose textbook was so justly admired by Dr. Osler, in his 1881 edition said that angina pectoris involves, as an essential feature, neuralgia and might be included among diseases of the nervous system. "It has been observed," he said, "in cases in which the coronary arteries are obstructed by calcification or other lesions, but obstruction of these arteries is not essential to its occurrence, as was at one time supposed." His chapter is still worth reading for its clinical details. A few years later, in the chapter on Angina Pectoris in Pepper's *System of Practical Medicine* (vol. 3, 1885), Flint said "The pathological condition on which the angina depends is ischemia of the heart" and he named coronary disease as the probable basis. For the explanation of the pain he referred to the intense pain in the limb which follows embolism of the femoral artery. It seems certain that Dr. Flint's later views were influenced by his association with Dr. W. H. Welch, pupil of Cohnheim and close friend of Carl Weigert. The author of the section on diseases of the coronary artery in Pepper's *System* (vol. 3, p. 828) said it was "doubtful if a diagnosis could be arrived at."

The earliest examinations of the heart after death in angina were made by physicians and surgeons, and in some cases, as Corvisart's editor said, made hurriedly and often clandestinely. The microscope was not applied to such work until the middle of the nineteenth century, which explains the long continued reference to ossification of the coronary arteries. A new era began when the great pathologists of the nineteenth century, making formal autopsies, turned their attention to coronary and myocardial disease. Cruveilhier (1842) saw infarcts, as did Rokitansky (1856). Virchow expressed himself briefly but explicitly, as I have mentioned.

An interesting contribution to coronary pathology was made by H. Boettger, an asylum physician, in 1863. Having seen two examples of rupture of the heart, Boettger collected and analyzed reports of sixty-two cases. In thirteen cases coronary disease had been noted; the lesions included varices, atheroma and thrombosis. Healing occurred only after adhesions. Death was often sudden, but duration up to eighteen hours was observed. Often there was no warning—a fall, loss of consciousness, and death in a few seconds. Sometimes, before the fall, there was an anxious cry, and in twenty-one of thirty-four cases there were prodromal symptoms suggesting angina pectoris. Pain varied from dull pressure under the sternum to unbearable pain in the same region or in the left hypochondrium, left shoulder or left arm.

This contribution seems noteworthy now, but it did not definitely influence thought at the time and there was no distinct advance until Carl Weigert (1880)

opened a new era in pathology by setting up the conception of coagulation necrosis and by improvements of histologic staining. In his article "Ueber die pathologischen Gerinnungsvorgaenge," after speaking of renal infarcts, Weigert said: "Still more typical, perhaps, is another kind of infarction which strangely enough has not been at all considered (beachtet): infarcts of the heart muscle." He continued, and it is worth while to quote his words, "In atheromatous changes of the coronary arteries, not infrequently thrombotic or embolic obstructions form in the branches of the arteries. If the obstruction forms slowly, or at least in such wise that collateral channels exist, but not enough to keep up nutrition, a slow atrophy occurs with destruction of the muscle fibers without injury to the connective tissue. The muscle fibers that disappear are replaced by fibrous connective tissue, and the so-called chronic myocarditis is nothing else than such a process. We cannot speak of a disappearance of muscle fibers by 'compression of an inflammatory exudate' or by 'contraction of new-formed connective tissue masses.'" It is interesting that, although the principles of infarction and subsequent repair were quickly accepted by pathologists, "chronic myocarditis" continued to be used in textbooks on medicine and in clinical work generally just as it was when such processes were supposed to be of inflammatory origin. It would seem if we must continue "-itis," that we should abandon the old connotation and think of fibrosis rather than inflammation.

About the time Weigert was explaining infarction, Prof. Ernst Ziegler (1880), then in Tübingen, later in Freiburg, proposed "myomalacia cordis," softening of the heart, after the analogy of "encephalomalacia" or softening of the brain. He described the details in his widely used textbook with adequate references to the historical development of the subject, showing that the process was recognized by several authors although overlooked or misinterpreted by many.

Weigert in his article said that his colleague Karl Huber would report a series of cases, and that was done in 1882 in *Virchow's Archiv*. Huber gave abstracts of the histories of seventeen cases, chiefly in private practice, and described the infarcts in considerable detail. He believed that arterial disease was the primary cause of the infarcts, showed that chronic myocarditis was not a correct term, and asserted that angina pectoris and related symptoms, previously considered purely nervous, had an anatomic basis. Attacks came on after physical or emotional strain, once after attending a new Wagner opera. Besides stenocardia, asthma was sometimes present. Physical signs were rarely described, but irregular heart beat and pulse were noted, and sometimes sudden dizziness or temporary syncope on effort. Collapse, general coolness of the body, weakness and other symptoms were mentioned at times. Huber asserted that the cases represented an important and by no means rare sort of heart failure, centering around disease of the coronary arteries, the latter a part of general arteriosclerosis. Syphilis was present in some cases. Ziegler commented on Huber's article in a later number of *Virchow's Archiv* and asserted that the conditions were better known than Huber thought and that he, Ziegler, had often demonstrated the relations to his classes. He agreed with Huber anatomically and clinically.

John Lindsay Steven, clinician and pathologist, who had worked with Huber and Weigert in 1882, gave a

CORONARY OCCLUSION—DOCK

567

series of lectures in 1887 on "Fibroid Degeneration and Allied Lesions of the Heart, and their Association with Disease of the Coronary Arteries." A critical examination of the British literature on the topics named showed that in many reports the coronary arteries were not mentioned. Among important conclusions, based on sixteen cases in his own experience, Steven said "The influence of a morbid state of the coronary arteries must be taken into account in considering all diseases of the heart, but especially of the myocardium, and no examination of the heart can be regarded as complete which does not include a careful investigation of the state of those vessels." Also "The possibility of diagnosing fibroid disease and infarction of the heart should always be kept in sight and, by carefully passing in review the whole symptomatology and pathology of a given case of cardiac disease, a correct opinion in this regard may probably be arrived at."

In 1894 Steven reported twenty-one new cases out of 810 consecutive autopsies. In only three cases could the coronary arteries be said to be practically healthy. He concluded that the development of fibroid patches in the heart wall afforded the structural basis of a large number of cases of angina pectoris.

The work of more than a hundred years, of which I have tried to give a fleeting glance, was so diversified in method and conclusions that for a long time no progress seems to have been made. But by 1884 Professor Ernst Leyden, director of the First Medical Clinic in Berlin, was able to decipher a fairly complete picture, which he presented under the title "Ueber die Sclerose der Coronararterien und die davon abhængigen Krankheitszustände," in seventy pages of the *Zeitschrift für klinische Medizin* (vol. 7, pp. 458-486, 539-580). He clearly traced the course of discovery in anatomy and clinical features and showed how the early picture of angina faded while disease of the coronary arteries was not susceptible of clinical recognition and theories of neurosis sprang up. For a time angina was rarely mentioned in works on heart disease, and case reports were to be found under such titles as "cardiac apoplexy," "dilatation," "fatty heart" or "weakened heart." Then, while physiologists and pathologists were gathering observations, clinicians slowly added positive knowledge, with Leyden and his associates, and many others, especially in France and Germany, taking part in proving the relations of angina pectoris and coronary arteriosclerosis. From a picture of current clinical opinion he drew the conclusion that greater knowledge of cardiac physiology was needed, including more accurate study of functional phenomena. Leyden gave many references to contributions of French clinicians, especially Huchard and his school, and prepared the medical world for Huchard's work on Diseases of the Heart and Great Vessels, which appeared in 1889. As it is still used by students of the subject, it is not necessary to speak in detail, but I may point out that fifty years ago Huchard taught that true angina pectoris has as its anatomic cause arteriosclerotic narrowing or obliteration of the coronary arteries, resulting in ischemia of the heart muscle. He made an extensive study of all symptoms then known. With regard to the often troublesome gastric features, he advised that they be treated as angina pectoris, advice still much needed in home care and on the golf course. His discussion of the objections to the coronary theory is still suggestive.

It may well be asked, If the pathogenic relations of the coronary arteries were so well understood fifty years ago, why was not coronary disease more frequently recognized from then on and more accurately treated? One reason, I think, is that the facts were not quickly and widely diffused, and a reason for that is that many other novelties were presented to the medical world at the same time. To name only a few, typhoid, diphtheria, malaria, pneumonia and meningitis; the development of antiseptics and asepsis; the growth of borderline medicine and surgery; endocrine diseases; peptic ulcer, and appendicitis. What a contrast there was between the way we applied the facts of appendicitis, searching for patients with the condition in an early form and sending them to the operating room for autopsy in vivo, and those of cardiac infarction, handled symptomatically as it had been for a hundred years. At the same time we were working out the slow but rich development of the anatomy and physiology of the heart and the exact study of pharmacology and therapeutics, not yet ended.

OSLER'S POINT OF VIEW

It is interesting to see the attitude of a great contemporary, Dr. Osler, whose conception of coronary disease is sometimes referred to as deficient. When I began to work with him in 1887, after being with Virchow, Huber, Weigert, Leyden and others of the same period, I found him familiar not only with the early history of angina pectoris but with the newer and current papers on coronary disease in English, French and German, receiving the leading periodicals, and using the well stocked periodical room of the College of Physicians. We read and discussed Steven's lectures as they appeared in the *Lancet*. In the laboratory in the University Hospital that Dr. Osler and Dr. John Musser had installed, Dr. Osler had a small collection of hearts with diseased coronaries, including the one from the imbecile in Elwyn Institution, often referred to in lectures and books. In his autopsies he never failed to examine the main trunks and many branches of the coronary arteries. Besides obviously fibroid areas in the heart muscle, he always took cross sections of the papillary muscle in order to search for fibroid foci, with reference to coronary sclerosis. In the first (1892) edition of the "Practice," the section on Affections of the Myocardium begins: "A knowledge of the changes produced in the myocardium by disease of the coronary vessels gives a key to the understanding of many problems in cardiac pathology." He described anemic infarcts briefly but clearly, also fibrous myocarditis. He said that the symptoms of myocardial disease were notoriously uncertain and that angina was sometimes present in cases of fibroid heart. Angina pectoris was considered under cardiac neuroses, not as an independent disorder but as a symptom associated with a number of morbid conditions of the heart and vessels, more particularly with sclerosis of roots of the aorta and changes in the coronary arteries. He held that true angina was a rare disease and discussed some views as to its nature, such as neuralgia of the cardiac nerves, cramp of the heart muscle and tension of the ventricular walls. He thought Cohnheim's experiments did not throw much light on the etiology of angina pectoris. Pseudo-anginas he considered hysterical and when in doubt advised treating such cases

as true angina. He included angina among possible results of coronary disease. I still think these articles good textbook material, in advance of the times.

In the editions that followed he made frequent revisions. In the second (1895) edition he added, under myocardial disease, Allen Burns's theory, revived by Potain and others, of ischemia of the heart muscle, and intermittent claudication, and admitted tobacco angina as a rare but well recognized form of disease.

In the third edition (1898) he described the work of F. H. Pratt and added a paragraph on fragmentation and segmentation and modified considerably the section on angina. The fourth (1901) and fifth (1904) editions were not changed. In the sixth (1905) edition typographic alterations were made. Dilatation and hypertrophy were put in the section on diseases of the myocardium, and the text of that section was modified. The most marked change under angina was to replace pseudo-angina by "functional angina pectoris," but Huchard's table of differential diagnosis was retained. The seventh (1909) edition shows no change in myocardial disease or angina pectoris.

In 1897 he published "Lectures on Angina Pectoris and Allied States" and in it began the chapter on "Theories of the Disease" with the coronary artery. In the Lunnleian Lectures (1910) he again abandoned pseudo-angina. In chapter II he said "We are all united in the acceptance of the Jennerian view of the close connexion of lesions of the coronary arteries with the disease."

Having early accepted the coronary theory of angina, I sometimes thought Dr. Osler was not as enthusiastic about that as could be wished, but as I talked with him or read his productions I had a feeling that his position was a better one and that he was constantly seeking more light on all the details of the problem. I think that severe angina and infarction were less frequent say up to 1910 than now, certainly in hospitals. The difference of opinion of Osler and Allbutt as to frequency are difficult to explain, but similar differences can be found all through the history of the disease.

SYMPTOMATOLOGY AND PLAN OF TREATMENT

Even in 1910 the data for a diagnosis of coronary disease were not as complete as they were ten years later, and those who ventured a diagnosis of infarct were often in doubt, especially if the patient survived the attack or if, in case of death, there was no autopsy. Pericarditis as a helpful sign was rare or was rarely noted. The use of blood pressure observations was an early addition of some value, also the more accurate recognition of circulatory collapse, but it was not until Libman showed the great importance of leukocyte changes that we had a definite guide. Soon after, Fred Smith showed the value of electrocardiograms, and studies of the sedimentation rate furnished another gain. All these discoveries met Leyden's plea for better knowledge of symptomatology in anginal disease, and no one would have appreciated them more than Osler. He too would have welcomed the more recent studies on pain, including that in diaphragmatic hernia and on chemical changes in heart failure, but at the present time I think he would still show a desire for more light.

There is a wish for a better name than angina pectoris, but until we have more exact knowledge of the minute processes I see no reason for change. But whenever used it must be with the conviction that the name refers only to symptoms and demands a prompt

and thorough differential diagnosis to exclude all other causes of pain, or to assign them their significance. Its adoption also necessitates an exact and persistent search for evidences of coronary disease and a prompt and intensive plan of treatment to meet all possibilities. Angina pectoris cannot be given as a cause of death. Thanks to writers and speakers on the subject from the beginning of Herrick's work, there is a very notable ability on the part of the medical profession to recognize and care for coronary patients. I am not in favor of publicity that would cause needless alarm or lead to diagnosis by laymen, but from time to time one can see patients for whom a deeper search, as by an electrocardiogram, would be useful, and for sound advice in examinations of the apparently healthy and to all who seek information on their cardiac problems. In angina patients, and for those who have survived an infarction, we can often improve the outlook for the future by directing activity in ways to favor collateral circulation in the coronary system. Many cases, some of them extremely severe, show that a remarkable degree of recovery is sometimes attained without particular effort. There would probably be more if definite measures were always taken as to exercise and rest, diet and mode of life, and probably by medication based on investigations already made and still to be made.

THE "DEFUNCTIONALIZING" COLOSTOMY (DEVINE)

A RATIONAL PREPARATORY PROCEDURE FOR RESECTION OF LESIONS OF THE LARGE BOWEL

ALTON OCHSNER, M.D.

MICHAEL DEBAKEY, M.D.

AND

JOSEPH ROTHSCCHILD, M.D.

NEW ORLEANS

Fatalities following resections of the gastrointestinal tract are due primarily to peritonitis. Because the number and virulence of micro-organisms progress commensurably with the aboral distance from the cardia, peritonitis and mortality following operations on the gastrointestinal tract similarly increase. Shambaugh¹ observed in autopsy series that the incidence of peritonitis was 15.3 per cent in thirty-nine cases in which operations had been performed on the stomach and small bowel, whereas in a group of fifty-two cases in which operations were performed on the large bowel, peritonitis was present in 33 per cent. Although there are other factors influencing the mortality in gastrointestinal resections, the most important is obstruction, because of the consequent increased number and virulence of bacteria in the bowel and the decrease in the local and systemic resistance. Grey Turner² reported a mortality rate of 25.7 per cent in seventy one stage resections of the large bowel as contrasted with a mortality of 12.5 per cent in seventy-two multiple stage resections. Cheever³ showed that the relief of obstruction by means of a preliminary colostomy decreased the mortality rate from 24 per cent in fifty cases without

colostomy to 8.5 per cent in thirty-five cases with preceding decompression. Almost identical results were obtained by von Haberer,⁴ who reported 25 per cent fatalities in 172 cases without colostomy and 8 per cent fatalities in 109 cases with colostomy. Arthur Allen⁵ reports from the Massachusetts General Hospital a 6 per cent incidence of peritonitis in 400 cases of one stage resection of the large bowel and a 3.5 per cent incidence in 253 two stage resections of the colon. As demonstrated by these figures, the mortality rate has been reduced materially by the institution of preoperative measures. Generally, these have consisted of relief of obstruction only, without special attempts to decrease the bacterial flora of the involved segment. The procedures usually employed have been enterostomy, cecostomy, appendicostomy and lateral and double-barrel colostomy. On the other hand, operations on obstructed bowel still are attended with considerable risk, because of the danger of peritonitis as well as the interference with healing of the bowel wall which the inter-employed decompressive procedures affect relatively little, because they do not decrease the number of pathogenic micro-organisms.

As long as fecal contamination of a bowel segment occurs, there will be little decrease in the pathogenicity of the micro-organisms within the intestine. Whereas a double-barrel colostomy deviates a great part of the fecal stream, almost invariably some soiling of the distal segment occurs. Only by entirely excluding a segment of the bowel from fecal contamination can there be any material diminution in the bacterial content of the bowel. The complete isolation of the openings in the proximal and distal segments will prevent the entrance of feces into the distal portion.

Whereas the separation of the proximal and distal openings in the performance of a permanent colostomy was suggested by Mixer,⁶ credit for first emphasizing the importance of isolation of the two bowel openings as a preliminary decompressive and preparatory procedure belongs to Sir Hugh Devine⁷ of Melbourne, Australia.

The rationale of the Devine type of colostomy is dependent on the complete "defunctionalization" of the bowel distal to the colostomy. By completely deviating the fecal stream away from an involved portion of the bowel, there is obtained relief of obstruction and, equally or even more important, absence of fecal contamination, which results in marked diminution and even virtual disappearance of the micro-organisms. Devine has termed this "debacterialization." As emphasized by Devine, the safety of resection of a lesion of bowel under such circumstances is assured not only because of the decreased number or absence of pathogenic bacteria at the anastomotic site but also because of the normal blood supply and intestinal tone, both of which are necessary for optimal healing. It is the common experience of surgeons that healing of intestinal wounds is poor in those instances in which there is lowering of the local resistance of the bowel as a result of stasis, diminished blood supply, inflammatory

reaction in the bowel and decrease in intestinal tone. Whereas healing of intestinal wounds usually occurs promptly under ordinary conditions even though the normal pathogenic organisms are present in the bowel, much better healing can be secured following the use of the Devine colostomy because of the "debacterialization" of the involved segment. "Debacterialization" and "defunctionalization" of the involved segment not only favor optimal healing of an intestinal anastomosis but also, because of the increased operability which results following the complete subsidence of an inflammatory process, make possible resections which otherwise could not be done. Not infrequently a mass, which on preliminary examination appears to be inoperable because of its size and fixation, at subsequent exploration is found to be not only operable but also relatively easily resectable. As a result of complete "defunctionalization" of the colon there occurs, in addition to the local improvement in the lesion, general improvement in the patient. This is particularly true in patients with

Fig. 1.—Technic of colostomy originally devised by Devine: A, upper right rectus skin incision about 2½ inches in length. B, formation of long spur (from 4 to 5 inches) by approximating opposed surfaces of proximal and distal limbs of loop of transverse colon. C, through buttonhole openings, made 1 inch on each side of original skin incision and extending through subcutaneous tissue only, Ochsner clamps are passed and applied to bowel wall, which is severed with the cautery between the clamps. D, cut ends of bowel are drawn into the buttonhole openings by the forceps and wound closed around neck of loop. E, original skin incision is closed.

inflammatory lesions. We believe also that following the use of the Devine colostomy it is possible to perform much more extensive resections than would be considered otherwise, because the safety of an operation of such magnitude is much greater in an individual who has been well prepared and whose bowel is in an optimal condition.

"Debacterialization" of the involved segment can be hastened by mechanically flushing out the segment by the introduction of fluids—either saline solution or, as suggested by Devine, antiseptics—into the distal colostomy opening and allowing them to pass through the involved bowel. Occasionally, irrigation through the distal segment is not possible because of complete obstruction. In such instances we have found that the introduction of pure cultures of *Bacillus acidophilus* in the involved segment both proximal and distal to the obstructing lesion will quickly free the segment of pathogenic bacteria. It is extremely important to employ

fresh active cultures of *B. acidophilus*, as the usual commercial preparations are ineffective. It is also important to use large quantities of the cultures, because if employed in insufficient amounts they are valueless.

TECHNIC

The procedure as originally described by Devine has been modified by us in an attempt to simplify the technic and diminish the possibility of wound contamination. The operation described by Devine consists of

Fig. 2.—Authors' modification of technic of Devine colostomy: *A*, transverse skin incision in upper right rectus region. *B*, stabilization of two limbs of colon by traction on rubber tube passed through mesentery at apex of loop facilitates formation of spur.

making an upper right rectus incision about $2\frac{1}{2}$ inches in length (fig. 1 *A*), the formation of a long spur from 4 to 5 inches, (fig. 1 *B*) and the suturing of the parietal peritoneum around the neck of the loop. Buttonhole openings extending only through the subcutaneous tissue are then made 1 inch on each side of the original skin incision and Ochsner clamps are passed through these openings and applied to the bowel wall (fig. 1 *C*). The bowel wall is severed with the cautery between the clamps, and the cut ends are drawn into the buttonhole openings by the forceps (fig. 1 *D*). The original skin incision is then closed (fig. 1 *E*).

The obvious disadvantage of this procedure is the possibility of contamination from the cut ends of the bowel as they are drawn through the subcutaneous tissue into the buttonhole openings on either side of the original incision. In spite of cauterization of the severed ends of the bowel, asepsis cannot be absolutely assured. That this is an actual as well as a theoretical danger is demonstrated by the occurrence of wound infections in the first few cases in which this procedure was performed by us. Moreover, the applied Ochsner clamps (the distal one of which must remain in position for about one week postoperatively) are bulky, are awkward and limit the patient's movements. By slightly modifying the procedure we have overcome these disadvantages.

The skin incision is made transversely (about 8 to 9 cm. in length) instead of longitudinally (fig. 2 *A*). The purpose of making the skin incision transversely instead of longitudinally is to obviate the necessity of subsequently making separate buttonhole incisions for the proximal and distal ends of the bowel. Moreover, as the severed ends of the bowel may be placed at the respective ends of the skin incision which may be sutured between the bowel openings, the possibility of

wound contamination is avoided. The upper and lower flaps are mobilized slightly and retracted longitudinally. The incision in the rectus sheath is made longitudinally through its mid portion and the rectus muscle split. The peritoneal cavity is opened by incising the posterior rectus sheath and peritoneum longitudinally. Through this small incision a preliminary exploration may be accomplished readily by lubricating the gloved hand with sterile petrolatum or liquid petrolatum, as originally advocated by Devine. This simple procedure greatly facilitates introduction of the hand into the peritoneal cavity through such a small incision. The presence of metastatic involvement as well as probable operability of the neoplasm may be determined by this preliminary examination.

The next step in the operation is the formation of the colostomy. A loop of transverse colon is delivered into the wound, and the mesentery of the apex of the loop is ligated and divided for a distance of about 2 cm. A soft rubber tube is passed through this opening in the mesentery at the apex of the loop and traction on the tube stabilizes the two limbs of the colon (fig. 2 *B*). The two opposing surfaces of the bowel segments are approximated for a distance of about 10 cm. by a continuous suture of chromic 0 catgut, thus forming a spur (fig. 2 *B*). If difficulty is encountered in performing this because of a short transverse colon, the hepatic flexure may be mobilized and the ascending and transverse colon used to form the spur. Once the spur is formed, the connected limbs of the bowel are pushed back into the peritoneal cavity and the peritoneum and anterior rectus sheath are sutured around the neck of the loop.

At this stage, clamps are applied to the bowel. Ochsner clamps may be used and are applied transversely to the loop of the bowel with the handles directed caudally. Before applying the clamps we strip the bowel in order to empty the loop and decrease its diameter, thus facilitating puckering of the bowel at the site of application of the clamps. As emphasized by Devine, the openings in the bowel and also in the skin should be small to

Fig. 3.—Application of proximal and distal clamps to bowel wall in vertical manner. It should be observed that the bowel is puckered and applied as close to the hinged end of the clamp as possible. This facilitates the subsequent placing of the skin suture close to the bowel.

favor better control of fecal evacuation. The bowel is severed between the proximal and distal clamps by means of the cautery and placed in the respective ends of the skin incision, which is sutured between the two ends of the bowel. However, a special clamp has been devised which obviates the previously mentioned disadvantages of the forceps. This special instrument consists of two clamps, which may be held rigidly apart

at the required distance by means of an attachable horizontal bar. Each clamp consists of two jaws hinged at one end with a swivel thumb screw at the other end for bringing the jaws together with a crushing force. The crushing surfaces of the blades are serrated to prevent slippage of the crushed bowel wall. A metal blade the width of the clamp is hinged at one end on the upper surface of the two jaws. After the clamps have been applied and the bowel wall severed this metal blade is turned on its hinge, as the blade of a knife, to cover

Fig. 4.—Bowel wall severed with cautery between proximal and distal clamps and guards folded in position over severed ends of bowel, thus preventing completely the possibility of contamination during subsequent manipulation.

entirely the severed end of the bowel, and thus acts as a guard to prevent the possibility of contamination. To each clamp there is attached at right angles a side piece, which may be applied to a horizontal bar for the purpose of stabilizing and holding the clamps apart at the desired distance, thus obviating the tension on the suture line and the possibility of its being torn during manipulation.

In operation this instrument greatly facilitates the procedure. The proximal and distal clamps are applied to the bowel wall as illustrated in figure 3. When the clamp is applied, the bowel is puckered similarly as described and placed as close to the hinged ends of the clamp as possible. This facilitates the placing of the skin suture close to the bowel. It should be observed also that the clamps are applied in a vertical rather than a horizontal manner. This prevents subsequent rotation of the bowel as the respective openings are placed in position at each end of the skin incision. The bowel is severed with the cautery between the clamps, and the guards are folded in position over the severed ends of the bowel (fig. 4). The two clamps with the crushed bowel ends are now separated in a fanlike manner to lie transversely, the respective segments of the bowel being placed in the extreme ends of the incision. The separation of the bowel segments in these positions permits closure of the skin incision except for buttonhole openings at either end through which the puckered bowel ends protrude. The horizontal bar is applied to each side piece of the clamp. One end of the bar is attached rigidly to the side piece of one clamp by means of a square joint, whereas the other end is fastened by a sliding joint, which may be tightened once the two clamps are separated the required distance (fig. 5). The wound is then closed by suturing each end of the anterior rectus sheath around the neck of the approximated limbs of bowel (fig. 5). The edges of the skin incision between the proximal and distal ends of the bowel are finally approximated (fig. 6). Twenty-four hours later the proximal clamp as well as the hori-

zontal bar and the side piece of the distal clamp are removed because the two segments of bowel are fixed to each other by the "spur" suture. Only the distal clamp is necessary (fig. 7) for the purpose of maintaining proper position of the bowel ends and preventing their retraction until they become adherent to the abdominal wall. The distal clamp is not removed for one week or ten days because this period of time is required for adequate fixation of the bowel to the parietes. Immediately following removal of the distal clamp, irrigation of the involved segment can be instituted in order to cleanse the segment and hasten its debacterIALIZATION.

As suggested by Devine, occasionally it may be necessary in cases with complete obstruction and with considerable distention that a preliminary cecostomy be done as a decompressive procedure before the performance of a "defunctionalizing" colostomy. This was satisfactorily done in one of our cases. After cleansing and debacterIALIZATION has been accomplished, which requires from ten days to three weeks, resection of the involved segment can be performed safely because of absence of infection and because of normal blood supply and tone of the bowel.

In nonmalignant lesions in which resection of the involved segment is not urgent, it is desirable to allow a long period of time to elapse before extirpation of the bowel in order to permit the inflammatory process to subside completely. This is particularly true in cases of diverticulitis in which because of stagnation of fecal contents in the diverticula infection may persist even months after the colostomy. This is clearly illustrated by one of our patients with localized diverticulitis and cicatricial narrowing of the sigmoid, who had several exacerbations of sigmoiditis weeks following complete "defunctionalization" of the distal bowel. The resection is usually done through an incision in the lower left quadrant of the abdomen. Because of the "defunctionalization" and debacterIALIZATION with almost complete subsidence of all inflammation, extirpation of the involved segment and its regional lymphatics is possible.

Fig. 5.—The two ends of the bowel have been separated the desired distance and stabilized in this position while the wound is being closed, thus obviating tension on the suture line and possibility of its being torn during manipulation.

Reestablishment of continuity of the bowel is done by an end to end anastomosis with little or no danger of insufficiency of the suture line because of the optimal conditions under which the bowel is permitted to heal. There is no urgency in redirecting the fecal stream through the involved segment following resection. This is illustrated in one of our cases in which ten days after the performance of the anastomosis a barium sulfate enema showed a small defect at the line of anastomosis without any clinical manifestations of insufficiency of

the suture line. Two weeks later the defect had completely disappeared and the fecal stream was redirected through the distal segment. In this particular case had there not been complete "defunctionalization" of the colon there probably would have resulted at least a localized peritonitis. The complete debacterialization and "defunctionalization" permit the performance of not only more radical procedures, as mentioned, but also resection of lesions located just above the pelvic floor and reestablishment of continuity of the bowel by end to end suture. In many cases with low sigmoidal lesions, abdominoperineal resections can thus be obviated. In one of our cases the condition of the lesion in the lower sigmoid at the time of exploration during the performance of the colostomy indicated its inoperability. It was hoped, however, that "defunctionalization" and debacterialization would result in sufficient decrease in size and fixation to make excision possible. At the second operation it was found that whereas the growth had decreased somewhat in size it was still fixed posteriorly and extended well into the rectum, obviating resection and reestablishment of continuity of the bowel. An abdominoperineal resection of the rectum and sigmoid was decided on and during the freeing of the rectum from the left wall of the pelvis the rectum tore, causing spillage and contamination of the peritoneum. The material was immediately removed and although a possible peritonitis from this contamination was anticipated the postoperative course was exceptionally smooth, there being only a slight febrile reaction. Undoubtedly the reason the patient did not develop a peritonitis as a result of contamination was the relative debacterialization produced by the "defunctionalizing" colostomy. Had we known that the size of this lesion would not have subsided sufficiently to permit excision and reestablishment of continuity of the bowel, it probably would have been better in this particular case to perform a two stage abdominoperineal resection as suggested by Lahey.⁸

In the performance of the abdominoperineal resection the special clamps for use in our modification of the Devine colostomy can also be applied for the ends of

Fig. 6.—The edges of the skin incision between the proximal and distal ends of the bowel are sutured, thus completing the operation.

the divided sigmoid. Thus, once the clamps are applied and the bowel severed with the cautery between them, the guards are folded over the severed ends of the bowel, permitting handling of the bowel with absolute assurance of asepsis.

Before redirecting the fecal stream through the distal segment, one should determine patency and sufficiency of the anastomosis by barium enema and x-ray examination. Generally a minimum of two weeks should elapse before diversion of the fecal stream.

The reestablishment of the function of the distal colon is accomplished by crushing the spur between the proximal and distal limbs of the colostomy, by means of a specially devised enterotome which permits destruction of the opposing bowel walls without crushing the intervening skin between the colostomy openings. Whereas this may be done by the clamp devised for this purpose by Devine, it has been found to have certain disadvantages. It is bulky and inconvenient because of its weight and long handles which project above the skin surface. In an attempt to overcome these objections we have devised a special clamp which possesses lightness in weight, simplicity in design, facility in appli-

Fig. 7.—Twenty-four hours postoperatively the proximal clamp as well as the horizontal bar and the side piece of the distal clamp are removed. Because the two limbs of the bowel are held together by the spur suture, only the distal clamp is necessary for the purpose of maintaining proper position of the bowel ends and preventing their retraction until they become adherent to the bowel wall.

cation and convenience in operation. This enterotome, which has been described previously,⁹ consists of only two working parts (fig. 8) and is constructed of duraluminum to give lightness in weight. Its application is extremely simple and consists merely of introducing the blades into the respective colostomy openings and fitting the crossbars and screw of one arm of the clamp in their corresponding openings in the other arm (fig. 9). By turning the screw wheel, one causes the crushing blades to approximate each other. Its lightness in weight and the fact that the handles project only about 3 cm. above the skin surface make it extremely convenient. An ordinary dressing may be applied and the patient may walk about during the several days required for the blades to cut through the spur.

We have used this procedure in twenty-six cases, in ten of which malignant lesions of the bowel involved the sigmoid or rectosigmoid, and in sixteen the lesions were nonmalignant. Of the latter sixteen cases there was one of diffuse ulcerative colitis in which an enterostomy of the Devine type was performed in the terminal ileum. There were two cases of sigmoidal diverticulitis with cicatricial narrowing of the bowel. One was a sigmoiditis unassociated with diverticulitis. There were two sigmoid fecal fistulas, both of which followed hysterectomy done elsewhere. One of these was associated with a tuberculous endometritis. In this instance the tuberculous infection may have been responsible for the persistence of the fecal fistula. In the other case because of extensive injury to the sigmoid at the time of hysterectomy a colostomy was performed in the upper sigmoid with blind closure of the distal rectosigmoid. In the remaining ten of the nonmalignant group there were rectal strictures produced by venereal lymphogranuloma.

In eleven of the sixteen cases of nonmalignant diseases, only the preparatory "defunctionalizing" colostomy has been done. As mentioned before, long periods of time are allowed to elapse before resections in inflammatory lesions. In eight of these eleven are rectal

8. Lahey, F. H.: Two Stage Abdominoperineal Removal of Cancer of the Rectum, *Surg., Gynec. & Obst.* 51: 692 (Nov.) 1930. Lahey, F. H., and Cattell, R. B.: Two Stage Abdominoperineal Resection of the Rectum and Rectosigmoid for Carcinoma, *Am. J. Surg.* 27: 201 (Feb.) 1935.

9. DeBakey, Michael, and Oschner, Alton: A New Clamp for the Devine Colostomy, *Surgery* 5: 947, 1939.

strictures due to venereal lymphogranuloma, and in one is an associated rectovaginal fistula. In two there are diverticulitis and cicatricial stenosis of the sigmoid. Trauma to the sigmoid occurred in one during hysterectomy for tuberculous endometritis. In five of the cases of nonmalignant lesions resections of the disease processes have been done. The patient with ulcerative colitis has had a total colectomy with a permanent enterostomy. Two had resections of the rectal stricture produced by venereal lymphogranuloma. One had a localized sigmoiditis with cicatricial narrowing without diverticulitis. One who had had a previous resection of a considerable portion of the sigmoid and blind closure of the rectosigmoid stump because of operative injury to the sigmoid during performance of hysterectomy has had successful implantation of the sigmoidal loop into the blind rectal segment beneath the peritoneal floor. All of these except the patient who had total colectomy for ulcerative colitis had reestablishment of continuity of the bowel.

Of the ten cases in which there were malignant lesions the tumor was located in the sigmoid or rectosigmoid in all but one, in which it was situated in the splenic flexure. In six of these ten cases, resections of the involved segment had been done. Three were found to be inoperable at the second operation so that the "defunctionalizing" colostomy was left as a permanent one and there was one death following the colostomy. Of the six cases in which extirpation of the malignant lesion was accomplished there was return of normal

were for nonmalignant lesions. Three patients with malignant lesions had subsequent explorations but the lesion was found to be inoperable so that the defunctionalizing colostomy was left as a permanent one. One patient with a malignant lesion died following the performance of the colostomy.

This fatality was apparently the result of overzealous postoperative therapy:

A Negro aged 56 was admitted to Charity Hospital with a history of acute intestinal obstruction of four days' duration. His abdomen was markedly distended and in the left lower quadrant a large palpable mass was present. X-ray examination following a barium sulfate enema showed complete obstruction in the sigmoid. Following twelve hours' preoperative preparation with Wangenstein duodenal suction, a Devine colostomy of the transverse colon was performed. There was considerable edema of the mesentery and distention of the bowel which made the operation difficult. The clamp on the proximal limb was removed after twenty-four hours and the immediate postoperative convalescence was satisfactory in that the postoperative febrile reaction returned to almost normal within four days. There was, however, retraction of the medial portion of the proximal opening probably resulting from the subsidence of the edema. There was also considerable relief in abdominal distention. Because on the sixth postoperative day the attending surgeon thought there was insufficient evacuation from the proximal opening in spite of diminished distention, an attempt was made to introduce a catheter into the proximal opening, which because of the retraction of the medial portion of the proximal opening resulted in a false passage of the catheter into the peritoneal cavity. Shortly thereafter the patient suddenly went into shock and exhibited manifestations of peritonitis. Death followed in twenty hours. Unfortunately an autopsy was not obtained but apparently death was a result of massive intraperitoneal contamination. It is our opinion that this could have been obviated had there been no postoperative manipulation of the wound. It is possible that it would have been better because of the complete obstruction and marked distention to have performed a preliminary cecostomy as suggested by Devine. The subsidence of the distention and edema of the bowel was probably responsible for retraction of the medial part of the proximal opening.

SUMMARY

The technic of the "defunctionalizing" colostomy originally described by Devine has been modified. The performance of the colostomy is greatly facilitated by a specially devised clamp.

This procedure was employed in twenty-six cases. There were malignant lesions of the bowel in ten of this group involving the sigmoid or rectosigmoid, and nonmalignant lesions in sixteen.

In six of the ten cases in which there were malignant lesions resection of the involved segment resulted in return of normal bowel function except in two cases, in which the lesion in the rectum obviated reestablishment of bowel continuity.

Resections of the disease processes in five of the sixteen cases in which there were nonmalignant lesions resulted in return of normal bowel function except in one, in which a total colectomy was done.

There was only one death in the total series and this followed the colostomy and probably was preventable.

Fig. 9.—Diagrammatic illustration of assembled enterotome in position in the colostomy.

Fig. 8.—Authors' enterotome for crushing the spur between the proximal and distal limbs of the colostomy to reestablish function of the distal colon. The instrument, which is constructed of duraluminum to give lightness in weight, consists of two arms, the upper part of which serve as handles and the lower part as crushing blades. Two right-angle cross bars are rigidly attached to the handle of one arm of the clamp and corresponding openings are present in the other arm of the clamp, through which these cross bars slide. The screw-bar provided with a wheel is also firmly attached to one arm of the clamp, with a corresponding screw opening in the other arm of the clamp.

bowel function except in two cases in which the lesion in the rectum obviated reestablishment of bowel continuity.

Of the total series of twenty-six cases only the "defunctionalizing" colostomy was done in eleven, in which there were inflammatory lesions. Of the eleven patients who had the second stage completed, all recovered. Six were for malignant lesions and five

THE HEART IN ANTHRACOSILICOSIS

JOHN F. GIERING, M.D.

WILKES-BARRE, PA.

AND

ROBERT CHARR, M.D.

PHILADELPHIA

Congestive heart failure is a common occurrence in cases of far advanced anthracosilicosis. In a series of postmortem examinations made on anthracite miners,¹ heart disease was found to be twice as common in the miners as in nonminers. At the White Haven Sanatorium it was noted that the most common symptom of the anthracite miners was dyspnea of varying severity, and it was difficult at the time of admission to determine whether this dyspnea was due to cardiac insufficiency or to anthracosilicosis. Attempts have been made to determine whether dyspnea in such cases is cardiac or pulmonary in origin by studying the vital capacity, the venous pressure and the velocity of pulmonary circulation in addition to considering carefully the history and the physical evidence.² It was noted in these studies that an estimation of the pulmonary circulation time was an aid in detecting failure of the right side of the heart. However, this test was found to be inaccurate in several instances, and prolongation of the time was found only in the cases in which definite heart failure was present.

In the present study only the miners without clinical evidences of congestive heart failure were studied. Attempts had been made to detect early pathologic changes in the heart secondary to anthracosilicosis by using the electrocardiographic as well as clinical and laboratory studies.

MATERIAL

Twenty-five miners were studied. Sixteen had anthracosilicosis without complicating pulmonary tuberculosis. Nine had either moderately advanced or far advanced pulmonary tuberculosis in addition to anthracosilicosis. The condition of the heart in these two groups was studied.

METHOD

The past and present medical histories of the miners were carefully investigated with a view to discovering past infection which might have had some influence on the heart. Thorough physical examination of the lungs and heart was made and the presence of any abnormal signs noted. A urinalysis, Mosenthal test, Wassermann test and blood count were made. The venous pressure was determined in every case by the method of Moritz and von Tabora,³ the vital capacity by the method of Peabody and Wentworth,⁴ and the pulmonary circulation and complete circulation times by means of paraldehyde, 0.8 cc. (Candel⁵), and a 20 per cent solution of calcium gluconate, 2 cc. (Baer and Slipakoff⁶). In each case a roentgenogram of the heart was made at a distance of 6 feet. Functional tests were performed, such as counting the pulse rate with normal respiration, after deep inspiration and after a "stepping" test with a view

to estimating how well exertion was tolerated. Electrocardiographic studies were made by one of us (J. F. G.), using the three conventional leads and six precordial leads as advocated and recommended by the Committee on Precordial Leads of the American and British Heart Associations. Examinations of the eyegrounds were made with a view to determining the presence or absence of arteriosclerosis.

RESULTS

The ages of the miners varied from 36 to 67. The duration of their occupation varied from three to forty years. All the miners had either moderately or far advanced anthracosilicosis, as evidenced by either nodular or massive consolidation in the lungs revealed by roentgenographic examinations. Eleven, in addition to anthracosilicosis, had either moderately or far advanced pulmonary tuberculosis. The results of urinalysis in all the cases were practically normal. The Mosenthal tests were negative. A Wassermann test of the blood was positive in two cases. The blood counts showed secondary polycythemia in most instances, the number of erythrocytes varying from 5.6 to 6.7 million. In these cases the hemoglobin content as estimated by Sahli's method was more than 100 per cent. Secondary polycythemia was common in association with nontuberculous anthracosilicosis.⁷ In cases of anthracosilicosis complicated by very far advanced pulmonary tuberculosis it was infrequently encountered.

The vital capacity was reduced in all cases from 20 to 70 per cent and in direct proportion to the extent of the anthracosilicosis.

Estimation of the venous pressure showed that in most cases it was within the normal limits, which, according to Moritz and von Tabora, are 4 and 10 cm. of water. In only four cases was the venous pressure somewhat above the normal, and even in these cases there was no definite clinical evidence of right-sided heart failure. There was no evidence of edema of the ankles or pulmonary congestion. In eight cases the edge of the liver could be palpated below the right costal margin on deep inspiration. However, in no case was the liver considered to be enlarged secondarily to cardiac decompensation.

The velocity of the pulmonary and of the complete circulation were practically normal in all the cases. For estimation of the pulmonary circulation time, Candel advocated using at least 1.4 cc. of paraldehyde. However, we found that this amount produced dangerously excessive coughing, which in a few instances was followed by extreme shortness of breath. In this study we reduced the amount of paraldehyde to 0.8 cc. and the results were quite satisfactory. The normal pulmonary circulation time, according to Candel, is from 3 to 9.5 seconds. The complete circulation time was determined, 2 cc. of a 20 per cent solution of calcium gluconate being used. Baer and Slipakoff found that the normal complete circulation time varied from nine to sixteen seconds.

Roentgenographic examination of the heart showed no enlargement except in two cases. In these there was an increase in the transverse diameter both to the right and to the left, more marked on the right side. The pulmonary conus was prominent in one case. The aortic knob was prominent in most, with a suggestion of calcification of the aorta in four cases.

The examinations of the eyegrounds showed early or advanced arteriosclerosis in all the cases.

7. Cohen, A. C.: Unpublished data.

The electrocardiographic studies showed the following deviations from the normal in the standard leads:

CASE 1.—*Age 51, moderately advanced anthracosilicosis.* P₁ was inverted. The PR interval was increased. The amplitude of T₁ and T₂ was low. ST₁ took off about 1 mm. above zero level. QRS₁ was of low amplitude. There was slight slurring of QRS₂.

CASE 2.—*Age 48, moderately advanced anthracosilicosis.* P was iso-electric in the three standard leads. T₁ and T₂ were iso-electric. T₃ was of low amplitude. There was slight slurring of QRS.

CASE 3.—*Age 37, moderately advanced anthracosilicosis.* ST₁ was concave. ST₁, ST₂ and ST₃ took off from 1 to 2 mm. above the zero level. Sinus tachycardia was present.

CASE 4.—*Age 45, moderately advanced anthracosilicosis.* A "coronary" type of ST₁ was present. There was slight convexity of ST₂. ST₃ was concave. The three conventional leads, together with the precordial leads, were diagnostic of anterior coronary occlusion. Q₃ measured more than 25 per cent of the largest amplitude of QRS shown in any lead of this record. Sinus tachycardia was present.

CASE 5.—*Age 60, far advanced anthracosilicosis.* QRS₂ and P₃ were of low amplitude. T₃ was iso-electric. ST₁ was concave. There were sinus tachycardia and left axis deviation.

CASE 6.—*Age 59, far advanced anthracosilicosis.* T₃ was of low amplitude. P₃ was iso-electric. Sinus tachycardia and left axis deviation were present.

CASE 7.—*Age 58, far advanced anthracosilicosis.* P₁ was iso-electric. QRS₁ was of low amplitude. There was an occasional auricular extrasystole.

CASE 8.—*Age 51, far advanced anthracosilicosis.* P₂ was abnormally high. P was peaked. There were slurring of QRS and right axis deviation.

CASE 9.—*Age 36, far advanced anthracosilicosis.* There was coarse notching of QRS₃, and QRS₂ was of low amplitude.

CASE 10.—*Age 67, far advanced anthracosilicosis.* P was of low voltage. There was slight slurring of QRS₁ and QRS₂. QRS₃ was of low amplitude, with coarse notching. T₃ was of low amplitude. There was left axis deviation.

CASE 11.—*Age 53, far advanced anthracosilicosis.* P₁ was iso-electric. T₁ and QRS₁ were of low amplitude. QRS₁ was slurred and notched. There was slight slurring of QRS₂ and QRS₃. Lead 1 showed definite abnormalities.

CASE 12.—*Age 58, far advanced anthracosilicosis.* The PR interval was increased. T₁ was of low amplitude. QRS was of low voltage, with coarse notching. There was left axis deviation.

CASE 13.—*Age 61, far advanced anthracosilicosis.* ST₁ was concave upward. It took off 2 mm. above the zero level. ST₂ took off 1 mm. above this level.

CASE 14.—*Age 56, far advanced anthracosilicosis.* P₂ was diphasic. ST took off 2 mm. above zero. There was slurring of QRS. QRS₂ was of low amplitude. Q₃ was notched and measured 16 mm. There was left axis deviation.

CASE 15.—*Age 44, far advanced anthracosilicosis.* P₂ and T₃ were inverted. P₁ and P₂ were peaked. ST₃ was convex upward and took off 1 mm. above zero. There were left axis deviation and sinus tachycardia.

CASE 16.—*Age 51, far advanced anthracosilicosis.* P₁ was of low amplitude. ST₁ was concave and took off 1 mm. above zero. There was slight slurring of QRS₃.

CASE 17.—*Age 50, moderately advanced anthracosilicosis with tuberculosis.* The PR interval was increased. ST₁, ST₂ and ST₃ were concave. The ST intervals in the three standard leads took off from 1 to 2 mm. above the zero level. QRS₁ and QRS₂ were of low amplitude. There was slurring of the down stroke of R₂. P was notched.

CASE 18.—*Age 53, moderately advanced anthracosilicosis with tuberculosis.* P₁, P₂ and P₃ were iso-electric. T₂ and QRS₂ were of low amplitude. QRS₁ was slurred. Sinus tachycardia and right axis deviation were present.

CASE 19.—*Age 62, moderately advanced anthracosilicosis with tuberculosis.* T₃ was of low amplitude. The QRS complex was of low voltage. P₁ was of low amplitude. Left axis deviation was present.

CASE 20.—*Age 42, moderately advanced anthracosilicosis with tuberculosis.* T₁ was iso-electric. T₂ and T₃ were inverted. P₁ and P₂ were peaked. ST₃ was convex. There were slight slurring of QRS₁, QRS₂ and QRS₃, right axis deviation and sinus tachycardia.

CASE 21.—*Age 38, moderately advanced anthracosilicosis with tuberculosis.* P₁ and P₂ were notched. T₃ was of low amplitude. ST₁ was concave upward and took off 1 mm. above zero. ST₂ took off 1 mm. above zero. There were slight slurring of QRS₁, left axis deviation and sinus tachycardia.

CASE 22.—*Age 48, far advanced anthracosilicosis with tuberculosis.* P in all leads was of low voltage. T₃ was iso-electric. QRS in all leads was of low voltage. ST in all leads was concave. ST₁ and ST₂ took off 1 mm. above the zero level. There were sinus tachycardia and left axis deviation.

CASE 23.—*Age 44, far advanced anthracosilicosis with tuberculosis.* T was of low voltage. There were occasional ventricular extrasystoles. Sinus tachycardia was present.

CASE 24.—*Age 42, far advanced anthracosilicosis with tuberculosis.* P₁, P₂ and P₃ were peaked. P₁ and P₂ were higher than the normal figure of 2 mm. as described by Pardee. T was of low voltage. ST₂ took off below the zero level. There were coarse notching of QRS₁, left axis deviation and sinus tachycardia.

CASE 25.—*Age 49, far advanced anthracosilicosis with tuberculosis.* T₂ and P₃ were of low amplitude. QRS was of low amplitude, with marked slurring. Sinus tachycardia was present.

It is of particular interest that of these twenty-five cases of cor pulmonale, in the majority if not all of which one would expect to find right ventricular preponderance (right axis deviation), this occurred in only three cases. On the other hand, left ventricular preponderance (left axis deviation) was present in ten cases. There was no axis deviation in twelve cases. Roentgenograms of the heart revealed no appreciable displacement of the heart in any of the cases. Axis deviation in this series was determined by the triangulation method of Einthoven.

Coronary occlusion was present in one case.

Indications of myocardial or vascular damage were low amplitude of individual waves and low voltage of the various complexes in the three standard leads, and they were present in all except cases 3, 9 and 25. Slurring and notching of the QRS complex were frequent. ST was of normal contour unless specified as being concave or convex. Convexity, concavity and high take-off of ST except in the case of coronary occlusion are of questionable significance. In no case was digitalis taken for at least two weeks prior to the taking of the electrocardiographic tracings.

Precordial leads were used in every case. We employed the new method advised by the Committee on Precordial Leads of the American and British Heart Associations. Lead 4F was used. Deviations from the normal were noted in many instances. The observations relative to these precordial leads will comprise the subject matter for another report.

The functional tests showed that practically all the miners studied had abnormal acceleration of the pulse rate after slight exertion, such as climbing two steps up and down from five to seven times. Along with the acceleration of the pulse rate they experienced marked dyspnea, in some cases so marked that an estimation of the vital capacity could not be made. In seven cases the pulse rate decreased after deep inspiration; in the

rest it either remained about the same or became even faster. Normally it should decrease from ten to eighteen beats a minute with the chest held in full inspiration.

SUMMARY AND CONCLUSIONS

Of twenty-five miners studied, sixteen had anthracosilicosis without pulmonary tuberculosis. Nine had either moderately advanced or far advanced pulmonary tuberculosis in addition to anthracosilicosis. They ranged in age from 36 to 67 years, and the duration of their occupation as miners ranged from three to forty years. Roentgenograms of the heart showed that two had cardiac enlargement. Secondary polycythemia and reduction of vital capacity were frequent occurrences. No appreciable variation from the normal venous pressure and pulmonary and complete circulation time was noted.

The electrocardiograms in the majority of instances showed myocardial damage. We feel that electrocardiographic examinations are of distinct value in the study of anthracosilicosis and that these examinations together with the clinical and laboratory observations described in this report would be of value in recognizing early cardiovascular damage secondary to anthracosilicosis with or without complicating tuberculosis.

THE CLINICAL VALUE OF THE ELECTROCARDIOGRAM

AN ANALYSIS OF 100 PRIVATE CASES

SOLOMON STROUSE, M.D.

LOS ANGELES

LOUIS N. KATZ, M.D.

AND

HERBERT F. BINSWANGER, M.D.

CHICAGO

Inevitably, whenever a new procedure of diagnosis or therapy is developed or gains rapid popularity, the pendulum swings too far and the procedure is apt to be employed in clinical practice beyond its indications. This appears to be true of electrocardiography, which recently has rapidly advanced the ability to interpret damage to the heart, especially that variety which accompanies disease of the coronary vascular system. There is a tendency today to rely too much on the electrocardiogram for the final interpretation of the condition of the heart at the expense of a careful history and an accurate clinical examination of the patient. The fault is less applicable to the cardiologist than to the general practitioner. In many places this trend has gone so far that surgeons require a routine preoperative tracing, believing incorrectly that it will by itself establish the margin of cardiac safety before operation. Eventually this overswing will rectify itself, but the tendency should be checked early so that overenthusiasm will not bring discredit to the real value of the electrocardiogram.

Experience has shown that, when electrocardiography is indicated, considerably more information can be obtained by the use of serial curves with the inclusion of chest leads. This fact became apparent to us both in the course of our clinical private practice and in the course of electrocardiographic interpretation, and it therefore seemed desirable to test it more accurately by

systematically reviewing a series of private patients who had been followed for many years and on whom many electrocardiograms had been taken.

The advantage of studying private rather than clinic patients obviously lies in the ability to carry through more sustained and continuous observation. Thus, some of the records used in this study were begun twenty-five years ago for patients who have been under constant supervision, and some of these patients have had ten or more electrocardiograms. The many problems in diagnosis, therapy and, especially, prognosis arising in the course of private practice present a more intensive opportunity for appraisal of the ultimate value of various complementary aids than is possible when the study is limited to data collected by many observers.

The purpose of an assay such as ours would be defeated by studying patients selected on the basis of the electrocardiographic evidence or of the necropsy. While both methods have been useful and several excellent reports of such studies have appeared, they place the emphasis in the wrong place as far as an assay of the value of the electrocardiogram to the patient is concerned. We are convinced that studies such as ours are essential and should be pursued further if the practical value of this objective aid to clinical practice is finally to be determined.

METHOD

One hundred clinical records with electrocardiograms were selected at random, without reference to diagnosis, from our files on private patients. We believe that this series represents a fair sample of cases in a general medical practice.

The clinical records and the electrocardiograms were studied independently. First the patient's records were reviewed, the clinical course of each patient was abstracted and the important developments were noted. Then all the electrocardiograms were reviewed and reinterpreted without regard to original interpretations or clinical notes. The data so assembled were restudied, and from the combined notes an attempt was made (1) to see how closely the electrocardiographic evidence approximated the clinical impression and (2) when there was sharp divergence between this evidence and the clinical impression, to determine from the subsequent course of the patient's illness which was more nearly correct and, if there was an error, in what direction it lay. Another review was then made with particular attention to records showing disagreement between the electrocardiograms and the actual course of events.

RESULTS

Statistical treatment of 100 miscellaneous records gives but little information. Nevertheless, some value is obtained from a tabular summary of our correlation, as is shown in the accompanying table. These figures and others given are intended merely as an indication of trend. In this series no case of rheumatic heart disease and only one of syphilitic heart disease was found. The majority of patients grouped themselves into (1) those complaining of precordial pain or distress, (2) those having diabetes mellitus, hypertension or generalized arteriosclerosis and (3) those requiring electrocardiograms to help exclude the possibility of disease of the heart. In this last group are included (a) patients with diseases such as cholelithiasis, bronchial asthma and arthritis and (b)

patients with vague symptoms and signs on whom the electrocardiogram was taken as a routine in differential diagnosis.

ROUTINE ELECTROCARDIOGRAMS IN THE ABSENCE
OF CLINICAL EVIDENCE OF HEART DISEASE

With regard to the last group, our study suggests that only rarely does a routine electrocardiogram aid the clinician in arriving at a judgment of the condition of the heart. Occasionally the nature of an arrhythmia will be diagnosed by the electrocardiogram or the clinical impression will be confirmed or altered and, depending on the nature of the arrhythmia, the prognosis will be modified. In the arteriosclerotic age group, serial electrocardiograms were an important index of the aging processes in the coronary blood vessels and sometimes seemed to indicate these changes before any clinical evidence was manifest. Furthermore, the rate of change of the contour of the electrocardiogram when a series is taken aids in judging the rate of progress of such coronary disease. We have abundant evidence showing that slight electrocardiographic changes occur from year to year in patients who give no other evidence of a changing status. This coincides with the results obtained from analyses initiated on the basis of electrocardiographic contour.¹ Therefore we firmly believe that the periodic examination of patients more than 40 years of age should include an electrocardiogram with two or more chest leads and that such examinations should be repeated yearly.

*Correlation of Electrocardiographic Interpretation in 100 Cases
with the Conclusion Arrived at from the Clinical Evidence*

Electrocardiographic Interpretation	Total Number of Cases in Group	Number of Cases in Which Electrocardiographic Evidence	
		Coincided with Clinical Evidence	Differed from Clinical Evidence
A. Within normal limits.....	23	16	7
B. Probably within normal limits...	3	3	0
C. Borderline record.....	9	9	0
D. Probably abnormal.....	11	8	3
E. Definitely abnormal.....	54	46	8
Total.....	100	82	18

Positive evidence, even when slight, usually indicates underlying pathologic changes in the heart, although these may be only transitory reversible abnormalities. Pardee² recently has found a similar correlation between electrocardiographic and postmortem observations. Sometimes, with patients having diseases elsewhere than in the heart, the differentiation of cardiac from extracardiac factors may be aided by the electrocardiogram.

In systemic diseases in which heart disease of an arteriosclerotic nature is common, the need for periodic examination with electrocardiograms is even greater. The electrocardiogram properly correlated with the clinical observations aids in judging the progress of the coronary disease, in the case of hypertension, serial electrocardiograms may aid in determining the presence and progression of hypertrophy; but as a rule x-ray and clinical evidence is much better.

In the foregoing discussion we take for granted that the interpretation is made by a competent medical electrocardiographer on the objective evidence present in the electrocardiogram. Great care must be taken to pay attention to those minutiae which are of significance without reading into the electrocardiogram more than is present. These "minutiae" consist primarily of changes in the contour and direction of the QRS complex, the level of the ST segment and the direction, size and shape of the T wave, as well as the peculiar forms seen in cases of excessive treatment with digitalis and of coronary insufficiency.¹ Particular attention should also be paid to auriculoventricular and intraventricular block.

THE ELECTROCARDIOGRAM AS AN AID IN EVALUATING
SUBSTERNAL PAIN AND DISTRESS

A much more serious problem arises with regard to patients with substernal pain or distress, a striking and common clinical phenomenon. These symptoms are listed by Smith, Rathe and Paul³ among the five major symptoms of coronary insufficiency. These authors state that 54 per cent of their patients, in whom the initial symptom was angina of effort, later developed coronary thrombosis. Saphir, Priest, Hamburger and Katz,⁴ in a study of thirty-four cases in which autopsy was performed, showed that half their patients with proved coronary occlusion had had pain referable to the heart. The current literature contains many comments and much disagreement as to the incidence of pain before or during a coronary closure. Levine,⁵ for example, has expressed the view that a careful history will reveal a story of pain in the vast majority of instances.

Naturally the incidence of substernal pain will depend on how the material for study is selected. The frequency of pain or distress will be less when the material is selected from a series of necropsies or from a series of electrocardiograms than when the study is initiated by selecting a series of patients. The last method of approach presents the best opportunity for diligent inquiry concerning precordial discomfort. This is particularly true of private practice, in which long clinical observation is possible. In hospital practice many patients are seen under circumstances in which it is not possible to secure a complete history. The true incidence of precordial pain can be estimated more accurately from a series such as we studied, in which more careful histories can be obtained. In our series, of a total of forty-two patients whose condition was diagnosed as coronary occlusion, all but two complained of substernal distress at some time in the past or during the episode. Even these two patients might have had pain.

Since the majority of our patients were studied because of pain of varying intensity, the major portion of this study resolves itself into an inquiry on the significance of substernal pain. Probably no more serious problem confronts the private practitioner than the determination of the cause of chest pain. The reorganization of the mode of life of the patient depends on the correctness of the diagnosis. In each of our cases a careful history and comprehensive physical examination were made before the electrocardiograms were taken. Since no practitioner can hope to attain

perfect efficiency in the diagnosis of precordial distress, the real problem lies in the ability of the electrocardiogram to assist in cases of doubtful diagnosis by helping to determine whether or not the heart is diseased.

Chest pain, as is well known, is not always due to coronary disease or coronary insufficiency. Pain may arise because of so-called psychoneurotic tendencies, as in neurocirculatory asthenia. It may be occupational, as in typists. It may be due to diseases of the spine or nerve roots, diaphragmatic hernia, abdominal diseases or lesions of lung or pleura. It is common with cardiospasm. Careful clinical observation is always needed to disclose all possible extracardiac causes of precordial pain. With the milder and atypical forms of chest pain the electrocardiogram will often be of value, but it is not always diagnostic, since (1) it is possible that organic heart disease may be present and the pain still be due to some other cause and (2) chest pain of cardiac origin does occur in some cases even in the absence of electrocardiographic abnormalities. Furthermore, in the more serious cases of sudden collapse, abnormalities may be found even when no coronary closure is present because the collapse may itself cause acute coronary insufficiency. However, subsequent electrocardiograms will help to disclose whether or not a myocardial infarction has developed.

Our study revealed three facts in this connection: 1. A single electrocardiogram unless it gives specifically positive results has no clinical value. 2. Positive electrocardiographic evidence will not always be of prognostic value, since in several instances the clinical picture and subsequent course gave no evidence of progressive myocardial disease. 3. Successive changes in serial electrocardiograms are the most important diagnostic aids of electrocardiography, particularly when chest leads are included. Many patients in our series have had a normal electrocardiogram immediately after an attack diagnosed clinically as angina pectoris. This is not surprising, since, as is well known, the abnormalities in the electrocardiogram quickly disappear when the attack is over. These normal records cannot be interpreted as an assurance of safety, and the clinical picture cannot be ignored. This is well illustrated by the history of a man aged 59 who was given a thorough physical examination, including the taking of an electrocardiogram, and showed nothing abnormal, yet two weeks later had a severe attack of angina pectoris. The electrocardiogram was normal immediately after the attack. Nevertheless the patient was put to bed on the basis of the clinical evidence and ordered to restrict his activities. Four weeks later he had a fatal attack of coronary occlusion with a typically diagnostic electrocardiogram.

This is not an unusual situation, but it serves to illustrate the importance of recognizing that electrocardiography in the presence of clinically definite angina pectoris fails to give evidence of underlying coronary disease between or even during attacks in about 25 per cent of all cases. Exercise tests help to increase the frequency with which coronary disease may be diagnosed from the electrocardiogram, but even when such tests are positive, normal five lead electrocardiograms may be obtained. This is equally true for patients with less definite precordial distress. It might be well to point out that the mildness or severity of the symptoms is not the significant factor in making a prognosis. Even a long series of electrocardiograms may not give evidence of coronary disease until the patient has a sudden coronary occlusion. It follows that the clinician should

never disregard definite or suggestive clinical observations because of negative electrocardiographic evidence. This is particularly true because coronary occlusion may occur without warning in the presence of a long standing negative evidence in the history, clinical picture and electrocardiograms.

This point of view should not be interpreted as an indictment against the electrocardiogram; it simply emphasizes that when reliance is placed exclusively on the electrocardiogram, without considering the clinical picture, serious errors are bound to occur. Ideally, the electrocardiogram or the series should be viewed objectively, the clinical picture should be assayed and then the two should be checked with each other, both reviewed again and then, and then only, a final judgment made. There is no short cut for clinical and common sense.

The cases in which the history, physical examination and clinical course caused us the greatest doubt and the gravest concern were unfortunately those in which the electrocardiograms were likewise of doubtful significance. To illustrate these difficulties we cite the case report of a man seen between the ages of 31 and 39 who had typical angina of effort and whose examinations revealed no physical defect. At least three excellent cardiologists saw this man in consultation, agreeing on a probable diagnosis of angina pectoris or small coronary occlusions. Five electrocardiograms were taken in the course of six years, and all but one were normal. He died at the age of 39 from carcinoma of the pancreas. The coronary arteries at autopsy showed only slight sclerosis. Even though the patient was constantly under observation, with frequent bouts of precordial pain, no objective evidence was obtained by any method of examination warranting a positive diagnosis of coronary disease. The slight coronary sclerosis found at autopsy may have been the explanation of the clinical picture.

Since approximately one half of the patients with substernal distress on effort later have coronary thrombosis, the physician's diagnostic efforts would be greatly aided by a definite diagnostic procedure. The electrocardiogram offers the best complementary aid but cannot be considered 100 per cent efficient. This opinion is well supported by our series and by reports of others.

Another patient, with an almost identical clinical history, illustrates the positive value of serial electrocardiograms. In 1928, at the age of 50, he first complained of definite precordial distress on effort, which has continued to the present. A series of ten electrocardiograms, starting in 1928, is attached to his records. The tracings of 1928, 1933 and February 1934 are normal. During this time he was having precordial pain on effort. Sept. 20, 1934, a more severe but less definite "attack" occurred. Electrocardiograms taken twelve hours afterward showed definite abnormalities. The S-T segment was depressed in all leads, T₂ was inverted, QRS₂ was taller, there was first degree auriculoventricular block, S-T₄ was iso-electric and horizontal and T₄ was smaller. In four days there was definite restoration toward normal, which continued through October 2. An electrocardiographic diagnosis of a small posterior myocardial infarct was made, confirming our clinical impression of atypical coronary occlusion. Since this attack the patient has been leading a restricted life but still has angina of effort. Electrocardiograms taken in 1936, 1937 and 1938 are normal. In short, a patient with constant more or less

severe anginal symptoms had many electrocardiograms taken in a ten year period, all of which were normal except a series of three taken during a more severe episode. In this case the serial electrocardiograms completed the diagnosis of coronary sclerosis with a small occlusion.

Evidence that coronary occlusion is rare in women who are not hypertensive or diabetic receives considerable support from our series of women, some of whom have been observed from ten to twenty-five years. Despite the complaint of indefinite precordial distress, clinical and electrocardiographic examination showed no deviation from normal and several of these women are still alive and active in their eighth decade.

By contrast we have observations on a few women who had indefinite precordial distress with normal electrocardiograms but who later had diabetes or hypertension. These patients showed changing electrocardiograms corresponding to their changing clinical conditions; most of them had final attacks of coronary occlusion.

Both groups indicate the great value of the electrocardiogram in substantiating clinical diagnoses and in establishing prognoses. This was true for women to a much greater extent than for men, as established statistical information would lead one to expect. Emphasis is again placed on the importance of serial studies. Unchanging normal electrocardiograms in women are of good prognostic value, whereas changes may indicate underlying pathologic conditions.

There is a more serious and unsatisfactory problem in the case of men with indefinite precordial pains not typically anginal. Although such men should not be separated too sharply from those with the typical anginal syndrome, the clinical problem is distinct. Patients with angina pectoris receive treatment for the condition regardless of the electrocardiographic evidence, but it is not always easy to determine a method of living for a man with indefinite precordial pains. In a few of our cases the serial electrocardiograms gave evidence of slowly progressive coronary disease, but in most of them (twelve) the electrocardiograms were either normal or on the borderline. Although patients have been followed for years, electrocardiographic evidence has been essentially negative or doubtful. We do not feel confident that such negative evidence is conclusive in ruling out the presence of coronary disease. Even though in the six cases of our series in which autopsy was performed the condition of the coronary arteries had been diagnosed correctly ante mortem by electrocardiograms, the autopsy studies of other authors⁴ indicate that coronary disease may be present without previous clinical or electrocardiographic manifestations. Therefore we believe it important to emphasize that a long series of electrocardiograms presenting negative or doubtful evidence does not by any means absolutely preclude the possibility of coronary artery disease.

INTERPRETATION OF THE ELECTROCARDIOGRAM

One of the difficulties encountered in interpreting the electrocardiogram is that of making the objective final judgment intelligible to the clinician. After some experience it has become the practice of one of us (L. N. K.) to make five gradations in the interpretation, to which the following significance has been attached:

1. "Within normal limits" means that the record is not abnormal for the age considered.

2. "Probably within normal limits" means that the record shows some deviation from normal but little significance need be attached to it.

3. "Borderline record" indicates that the record is on the borderline between normal and abnormal and may be of little value to the clinician in determining whether or not there is organic disease.

4. "Probably abnormal" indicates that there are probably abnormalities and that the tracing should carry some weight in making the clinical interpretation.

5. "Definitely abnormal" indicates definite abnormality not to be dismissed lightly.

These five gradations are an attempt at objective quantitative interpretation of the electrocardiogram independent of the clinical evidence. The clinician, aware of this evidence, should find the proper importance to be attached to the electrocardiogram. In no sense are these interpretations to be considered as a substitute for the clinical interpretation; they are rather to be considered as one part of the evidence in finally arriving at a complete clinical assay of the condition.

Certain forms of abnormality gain particular significance, viz. the characteristic curve of coronary insufficiency, of digitalis excess, of auriculoventricular block, of intraventricular block, of auricular fibrillation, of electrical alternans and of multiple premature systoles of several foci of origin. Experience has shown that special significance in most but not all instances can be attached when these particular findings are present in the electrocardiograms.

As the accompanying table shows, the purely objective interpretation of the electrocardiogram independent of the clinical evidence is far from a 100 per cent accurate process. For instance, seven of twenty-six patients with normal or probably normal electrocardiograms showed definite clinical evidence of heart disease at the time or indicated its presence from the subsequent course. Practically all of these had only three limb leads, without chest leads, and most had only one record. Several, however, had serial records and four leads without showing electrocardiographic evidence of cardiac damage. In nine patients with borderline electrocardiographic changes, the electrocardiogram was obviously of no value. More significant to us is the fact that eleven of the sixty-five patients with definitely abnormal curves had no clinical evidence of heart disease during the entire period of observation, although two had intraventricular block. For these eleven patients only a single record was obtained or, when a series was taken, the serial curves did not vary significantly. We can only conclude that a definitely abnormal electrocardiogram may not infrequently be associated with subclinical cardiac involvement and that if the electrocardiographic curve remains stationary the clinical course may be benign. It is important to recognize this fact; otherwise too much significance will be attached to electrocardiographic abnormalities.

In short, this study has demonstrated that, while the electrocardiogram is a useful tool in clinical practice, it constitutes only one part of the clinical examination, and that it must be correlated with the rest of the examination.

We should like to close by cautioning the clinical practitioner to resist the temptation to allow the electrocardiogram to make his diagnosis and prognosis for him. If he avoids this pitfall, a definite place in clinical practice is assured for this important clinical aid.

BALANTIDIASIS

MARTIN D. YOUNG, Sc.D.

Junior Zoologist, United States Public Health Service
COLUMBIA, S. C.

The rarity of reported cases of balantidiasis in the medical literature makes any new focus of infection worthy of note. Therefore when an active infection with *Balantidium coli* was found in a patient at the South Carolina State Hospital, an investigation was instituted to determine the prevalence of the parasite in a selected group of patients. The patients examined were those suffering from diarrhea and those with a mental condition which tolerated untidiness, as it was felt that if additional infections were present they were most likely to be found among these patients.

Usually two fecal specimens from each patient were examined, but the stools of patients found to be infected with *Balantidium coli* were examined repeatedly. A

Fig. 1.—Appearance of living trophozoite of *Balantidium coli* (A) in a fecal smear. An ovum of *Trichuris trichiura* (B) is shown for comparison. A negative print is used for contrast ($\times 300$ approximately).

simple saline smear preparation was used. No techniques of concentration of parasites were employed. A total of seven infections were found among the 142 patients examined. This represents an incidence of 4.93 per cent. Since only two examinations were made and the appearance of the parasites in the stools is irregular, as is shown hereafter, it is possible that some infections were not found.

REPORT OF CASES

CASE 1.—E. A., a white woman aged 61, was mentally deteriorated, anemic, mute, bedridden and untidy when admitted to the hospital in July 1935. The mental diagnosis on admission was psychosis with cerebral arteriosclerosis. About one year after admission diarrhea developed, which became chronic and sometimes produced a dozen stools daily. The stools were usually small and watery and contained flakes of mucus. Medi-

cation for diarrhea had not alleviated the condition. On examination of a loose stool in February 1938, numerous trophozoites of *Balantidium coli* were seen. Ova of *Trichuris trichiura* (whipworm) and *Necator americanus* (hookworm) and larvae of *Strongyloides stercoralis* were present also. Repeated fecal examinations over a three weeks period revealed that the recovery of *Balantidium coli* was variable; some stools did not show parasites. Examination of well formed stools usually gave negative results, whereas loose and diarrheic stools contained large numbers of the parasites.

At no time were cysts or precystic forms of *Balantidium coli* observed. There was little variation in the occurrence of worm ova and larvae in the stools during the period of examination.

CASE 2.—D. H., a white woman aged 42, on admission in 1920 had dementia praecox of the catatonic type. She was very untidy and filthy, with marked diarrhea. *Balantidium coli* was observed in the stool in April 1938. Ova of *Trichuris trichiura* and *Necator americanus* and larvae of *Strongyloides stercoralis* were present also. Eighty-nine examinations were made in the 177 days from April 18 to October 12, at which time treatment was instituted; trophozoites of *Balantidium coli* were found seventy-seven times and cysts eight times.

CASE 3.—H. K., a white woman aged 33, who had been in the hospital nine years, had dementia praecox of the hebephrenic type. She had a ravenous appetite, refused to talk, was very untidy and soiled herself on many occasions. She had chronic diarrhea of at least one year's duration and occasional dysentery. *Balantidium coli* was first observed in April 1938. Ova of *Trichuris trichiura* and *Necator americanus* and larvae of *Strongyloides stercoralis* were present also. Over a period of 180 days, thirty-five stools were examined; trophozoites of *Balantidium coli* were found thirty-three times. Numerous cysts were found in two stools.

An examination of the blood during the latter part of the observation period showed leukocytes 28,500, with polymorphonuclears 77 per cent, lymphocytes 21 per cent and eosinophils 2 per cent; erythrocytes 3,900,000, and hemoglobin 43 per cent.

CASE 4.—S. H., a white girl, was 19 years old when committed in 1932, with a diagnosis of dementia praecox of the catatonic type. She had had pellagra. She was untidy and destructive of property. Recent marked diarrhea, with from eight to ten stools a day, together with an occasional dysenteric stool, led to the first examination of the stools. Numerous trophozoites of *Balantidium coli* were seen, together with ova of *Trichuris trichiura* and *Necator americanus* and larvae of *Strongyloides stercoralis*.

Over a nineteen day period, eleven examinations of stools were made; trophozoites of *Balantidium coli* were found seven times. During this period no cysts were seen.

A blood count revealed leukocytes 10,250, with polymorphonuclears 65 per cent and lymphocytes 35 per cent; erythrocytes 2,110,000, and hemoglobin 32 per cent.

CASE 5.—J. T., a white woman aged 53, had been in the hospital intermittently since 1910, the mental diagnosis being mental deficiency (imbecility) without psychosis. In 1932 she received treatment for diarrhea. Since 1932 tuberculosis had been present. Recently she had been showing marked diarrhea. Oct. 22, 1938, she passed eight or ten stools, and the following day three stools were passed within an hour. Examination of one of these diarrheic stools revealed *Balantidium coli* and ova of *Trichuris trichiura* and *Necator americanus*. Two stools examined during one week both showed trophozoites of *Balantidium coli*.

Examination of the blood showed leukocytes 17,400, with polymorphonuclears 57 per cent, lymphocytes 39 per cent and eosinophils 4 per cent; erythrocytes 3,900,000, and hemoglobin 63 per cent.

CASE 6.—A. L., a white woman aged 50 who had been in the hospital for eleven years, had dementia praecox of the catatonic type. She was noisy, destructive, untidy and filthy in her habits. She had chronic diarrhea, which had recently become marked. *Balantidium coli* was observed in a purged stool after treatment with oil of chenopodium. Ova of *Trichuris*

From the Williams Malaria Research Laboratory of the United States Public Health Service, located at the South Carolina State Hospital. Dr. Bruce Mayne, U. S. Public Health Service, prepared the photomicrographs, and Drs. John Cuttino and Coyt Ham, South Carolina State Hospital, cooperated in the securing of materials.

trichiura and *Necator americanus* and larvae of *Strongyloides stercoralis* were also present. Over a period of five days, four examinations of stools were made and trophozoites of *Balantidium coli* were found each time. Three stools contained cysts also.

Examination of the blood revealed leukocytes 11,050, with polymorphonuclears 68 per cent, lymphocytes 31 per cent and

Fig. 2.—The trophozoite of figure 1 enlarged to show the peristome (P) ($\times 750$ approximately).

eosinophils 1 per cent; erythrocytes 3,810,000, and hemoglobin 57 per cent.

CASE 7.—J. W., a white woman aged 31, with dementia praecox of the catatonic type, was noisy, destructive, untidy and filthy in her habits and mentally was markedly deteriorated. She had had diarrhea accompanied by anemia for about two years. Oil of chenopodium was given for worms and living trophozoites of *Balantidium coli* were found in the purged stools. Hookworm and ova of *Trichuris trichiura* and larvae of *Strongyloides stercoralis* were present also. Four examinations over a period of four days each showed *Balantidium coli*. No cysts were observed.

Examination of the blood revealed leukocytes 9,950, with polymorphonuclears 76 per cent and lymphocytes 24 per cent, erythrocytes 3,600,000 and hemoglobin 60 per cent.

MORPHOLOGY

Balantidium coli is a ciliated protozoan parasite (figs. 1, 2 and 3). It is the largest protozoan parasitic in man and is generally thought to be the only ciliate parasitic in human beings.

The parasites are oval to egg shaped. The body is uniformly covered with cilia, the animal swimming with a forward rotary motion. It has a funnel-shaped cytostome near the anterior end through which it feeds. Two contractile vacuoles are present. Body wastes are discharged through the anal opening, the cytopyge. In stained specimens the small micronucleus, embedded in the shelter of the large dumb-bell shaped macronucleus, can be seen.

Measurements of 100 living quiescent trophozoites were made from one of the specimens. The length ranged from 54 to 146 microns, with a mean of 91.64 microns. The breadth ranged from 37 to 100 microns, with a mean of 57.25 microns.

The cysts are spherical to ovoid-spherical, many of them appearing as perfect spheres (fig. 4). They are protected by a transparent double wall. The parasite can frequently be seen rotating slowly within the cysts.

Twenty cysts from one stool specimen were measured. The length ranged from 47 to 64 microns, with a mean of 54.6 microns. The breadth ranged from 45 to 57 microns, with a mean of 51.5 microns.

LIFE CYCLE AND PATHOGENICITY

The accepted theory of infection is that cysts are swallowed. After excysting, the parasites establish themselves in the large intestine. The parasites are capable of penetrating the intestinal mucosa to form flask-shaped ulcers, similar to those produced by *Endamoeba histolytica*, which may undermine the epithelium (figs. 5 and 6). Extensive ulceration results in large areas of necrotic epithelium, which is shed and passed to the outside with blood, thus giving rise to balantidial dysentery. Active trophozoites are passed in large numbers during this stage.

In the present series of cases, 145 examinations of stools were made. Trophozoites were found 127 times,

Fig. 3.—High magnification of the trophozoite of figure 2, showing cilia (C) and peristome region (P); $\times 1,000$.

or in 87.5 per cent of the examinations. Cysts were found thirteen times, or in 8.9 per cent of the examinations. Usually if the stool was decidedly diarrheic only trophozoites could be found. The cysts were found in the firmer stools and, when present, were usually seen in great numbers, sometimes almost to the exclusion of the trophozoites.

EPIDEMIOLOGY

Nisbet¹ in reviewing the American literature found the following cases reported: three from Louisiana, four from Arkansas, three from New York, two from North Carolina and one each from Iowa, Minnesota, Mississippi, Oklahoma (the patient had lived in Kansas also), Massachusetts and Maryland. In his report, Nisbet described a case from North Carolina.

Fig. 4.—Living cyst of *Balantidium coli* in a fecal smear. (A) cyst wall, (B) outline of macronucleus ($\times 1,340$ approximately).

Logan² reported four cases from Minnesota. In 1924 McEwen³ reported a case from Kansas in which the symptoms extended over twenty-six years. Ford⁴ reported a case from Washington and referred to a case reported from New Mexico by Gant⁵ in 1915. In 1932 Mendelson⁶ found the infection in a native of New Mexico, and Scott⁷ in 1935 reported five cases of nonsymptomatic infection from West Virginia.

Thus until the present report, thirty-two cases had been reported from sixteen states in this country. Little⁸ in 1931, reporting a case from Canada, stated that fewer than 250 cases had been reported in the medical literature.

Meleney (personal communication in May 1938) reported two cases in Tennessee. These two cases and the seven cases from South Carolina reported in this paper make a total of forty-one infections found in eighteen states.

TREATMENT

The long list of medicaments which have been tried and recommended for this infection speaks for the lack of a universally accepted treatment. Cures supposedly

effected with one drug have not been duplicated in the hands of other clinicians. Therefore when the present study was begun there was no drug that could be relied on as being specific for these parasites.

Because of the similarity in pathogenicity of balantidiasis to amebiasis and because both causative agents are protozoa, it was decided to try a drug that has given good results in the treatment of amebiasis, viz., carbarsone. Patient 1, the first treated, was old and very weak, and therefore the drug was given in smaller doses than those employed in the treatment of amebiasis. One and one-half grains (0.1 Gm.) a day was given for four days, after which the treatment was interrupted for unrelated causes. Treatment was started again nine days later; on the fourth day the dose was increased to 3 grains a day (0.2 Gm.), which was given for five days. On the next to the last day of treatment the patient received $5\frac{1}{4}$ grains (0.3 Gm.) in two doses and on the last day $3\frac{3}{4}$ grains (0.24 Gm.) in one dose. The total time from the beginning to the end of treatment was twenty-two days, and the patient received a total of $34\frac{1}{2}$ grains (2.2 Gm.) of carbarsone given in fourteen days.

Trophozoites of *Balantidium coli* were found throughout the course of the treatment, but on the last day most of them appeared dead. Daily examinations for three weeks after the termination of therapy failed to disclose parasites. Examination of the stools gave negative results for five months, after which the examinations were discontinued.

Fig. 5.—Section of a large intestine of man showing ulceration caused by *Balantidium coli*. Nests of the parasites (A) can be seen at the base of the ulcer. (Material from the Philippines.)

Patient 2 was given 0.25 Gm. twice a day for ten days. Living balantidia were seen the first day after treatment. The next specimen was obtained on the sixth day of treatment and showed only dead balantidia. For one month thereafter no balantidia were seen.

The other patients are now under treatment.

The carbarsone seemed to have little effect on the parasitic helminths present.

Meleney, in a communication to me during August 1938, gave the results of treatment in one of the two cases found in Tennessee. The patient was a housewife living on a farm. She had been treated for pernicious anemia for four years. She had simple diarrhea ostensibly associated with the pernicious anemia. Balantidia were found in the stool in January 1926. The first course of treatment consisted of the administration of carbarsone by mouth, 0.25 Gm. twice a day for eight days. The balantidia disappeared from the stools and the diarrhea stopped. Dilute hydrochloric acid was given at the same time and may have been responsible for cessation of the diarrhea. The patient was readmitted to the hospital in April 1936, and balantidia were again present in stools. The diarrhea had recurred also. The patient was then treated with carbarsone, 0.25 Gm. being given by mouth twice a day for ten days and carbarsone enemas being given on alternate nights for four treatments. The latter part of the treatment consisted of a cleansing water enema followed by a retention enema with 2.0 Gm. of carbarsone dissolved in 200 cc. of 1 per cent solution of sodium bicarbonate. The balantidia disappeared after the third enema, which was given on the sixth day of the oral treatment. Stools were examined two weeks and three weeks later; no balantidia were found. Examination of the stools two years later (July 1938) revealed no balantidia.

In the South Carolina infections, as noted, oral treatment with carbarsone has been more effective than in Meleney's case. The stools of the first patient treated here were shown to be free from balantidia at all examinations made over a period of five months after the treatment. The stools of the second patient were still free from the parasites after a month. However, a number of patients must be followed over a long period to establish definitely that carbarsone provides a cure.

Oil of chenopodium administered orally to several patients was not efficacious in ridding them of the balantidia. One dose each was given to patients 4, 6 and 7, and two doses were given to patient 2. The balantidia were neither eliminated nor appreciably diminished in numbers by this drug, being found continuously before, during and after its administration.

Cort⁹ reported twelve *Balantidium coli* infections cured by rectal administration of oil of chenopodium. However, Serra¹⁰ reported the death of a child following the treatment used by Cort. It appears therefore that this drug, like many others, is not satisfactory for *Balantidium coli* infections.

COMMENT

Diarrhea and, occasionally, dysentery accompanied the infections reported. As the patients also harbored worms, which are capable of producing these symptoms, it cannot be said that the diarrhea and dysentery were due entirely to the balantidia.

However, in many of the reported cases in which *Balantidium coli* was the only etiologic agent, diarrhea and dysentery were present. The pathogenicity of balantidiasis has been definitely established by Walker¹¹ and others. This disease should merit more serious consideration.

9. Cort, E. C.: Infection with *Balantidium Coli*: Twelve Cases Treated with Oil of Chenopodium. *J. A. M. A.* 90: 1430-1431 (May 5) 1928.

10. Serra, A.: Balantidial Dysentery in Child: Death Following Rectal Administration of Chenopodium. *Porto Rico J. Pub. Health & Trop. Med.* 6: 443-444 (June) 1931.

11. Walker, E. L.: Experimental Balantidiasis. *Philippine J. Sc.* 8: 333-350, 1913.

The reports of *Balantidium coli* infections show the widest diversity in locality, climate, race, sex and age. Because of the wide scattering of the few human cases reported and because in many cases the infection has been associated with hogs, which show a high rate of infection, the idea is often expressed in the literature that man probably contracts the parasite from this animal rather than from human sources.

With this in mind, when the first infection was found here, the personal history of the patient was searched

Fig. 6.—Two of the parasites of figure 5 enlarged. The dumb-bell shaped macronucleus (B) can be seen in one of them.

carefully. It was found that she had lived on a farm for about forty-five years and had sometimes helped in the preparation of meats from freshly slaughtered hogs. Because of this possible source of infection, five members of her immediate family, who had lived under identical conditions, were given one fecal examination. None were found to be infected and none showed symptoms. Also it must be borne in mind that the symptoms of diarrhea did not occur in this case until after hospitalization of about one year.

Detailed personal histories and examinations of the families of the other patients were not obtainable.

Because of their mental condition, all the infected patients tolerated untidiness, both personal and environ-

mental. The clothing might become contaminated and often it was difficult to collect sufficient feces for an examination. The exercise grounds were polluted. This type of patient often puts rocks, leaves, sticks, grass, dirt and other débris into his mouth. Thus the factors necessary for the transfer of the infection from one person to another were present.

Although the chance of contracting the infection from hogs cannot be ruled out, it seems likely that the infections in these cases were contracted from human sources.

The factors for transmission of *Balantidium coli* are undoubtedly present in many places, especially where there is crowding or other conditions which make strict personal hygiene difficult. It is also likely that man is more frequently infected with this parasite than the few reported cases would indicate, many infections being overlooked or misdiagnosed.

SUMMARY AND CONCLUSIONS

1. Seven infections with *Balantidium coli* in white women were observed by me in South Carolina and two cases were found in Tennessee by Meleney.

2. The infected patients had chronic diarrhea and occasionally dysentery. *Trichuris trichiura*, *Necator americanus* and *Strongyloides stercoralis* were present also, and consequently the symptoms may not have been due entirely to the balantidia.

3. Frequent examinations of the stools were made in cases of infection. In 145 examinations, trophozoites were found 127 times, a percentage of 87.5. Cysts were found thirteen times, a percentage of 8.9.

4. Epidemiologic evidence indicates that the present infections were contracted from human sources rather than from hogs; swine are generally thought to be the source for most infections in man.

5. The balantidia disappeared from the stools of two patients treated with carbarsone. The stools of one patient were still free after five months. One month had elapsed since the treatment of the second and no balantidia had been seen. Oil of chenopodium given orally was not efficacious.

6. Few reports of this disease occur in the literature. Previous to this report, thirty-two cases had been reported from sixteen states. This report adds nine more cases, from two states.

7. The evidence indicates that the disease may be more prevalent than is reported.

Postoffice Box 1344.

ADDENDUM.—Since this manuscript was submitted for publication, two additional infections of *Balantidium coli* have been found at this hospital. This brings the total number of infections reported from South Carolina to nine.

Do the Neurotic Become Psychotic?—The hypothesis has frequently been advanced that many neurotic patients are in reality only early psychotic cases whose condition has not yet become acute. The essence of the theory is that certain neurotic conditions are in reality only early forms of psychosis. In an attempt to give evidence to this point Ross followed up his neurotic patients to find which were later certified as psychotic. Of the 1,186 neurotic patients, but fifty subsequently developed a psychosis, from which Ross feels that there is a possibility of a psychoses following a neurosis but that there is no ground for believing that psychoses and neurosis are different degrees of the same thing.—Landis, Carney, and Page, James D.: *Modern Society and Mental Disease*, New York, Farrar & Rinehart, Inc., 1938.

GRANULOCYTOPENIA CAUSED BY SULFAPYRIDINE IN CHILDREN

NATHAN ROSENTHAL, M.D.

AND

PETER VOGEL, M.D.

NEW YORK

Practically every case of granulocytopenia can be traced to an underlying sensitivity to certain drugs, such as aminopyrine, arsphenamine, dinitrophenol and, more recently, sulfanilamide. The introduction of sulfapyridine as a therapeutic agent in pneumonia has led to its widespread use. Wien,¹ experimenting with mice and rats, concluded that sulfapyridine is one fourth as toxic as sulfanilamide and that it has no apparent effect on the hemopoietic system. There is reason to believe that sulfapyridine is as toxic as sulfanilamide for the bone marrow, or more toxic, since we have observed ten cases of granulocytopenia (including one in a child) in the past two years. However, we have in the past few months observed three cases of granulocytopenia in children following the administration of sulfapyridine. This, in fact, is the purpose of the present communication—to call attention to the danger of employing sulfapyridine over prolonged or intermittent periods unless careful and frequent study is made of the blood picture. Two cases of granulocytopenia which occurred in adults during the administration of sulfapyridine have been reported in the British literature.² Barnett³ and Long⁴ have each mentioned a case which came under their observation.

There is no doubt that the following cases of granulocytopenia resulted directly from the use of this drug:

REPORT OF CASES

CASE 1.—*Recurrent pneumonia; monocytic granulocytopenia following intermittent use of sulfapyridine; recovery.*

John G., a baby aged 1 year, was admitted because of diarrhea Feb. 26, 1939, to the Lincoln Hospital.⁵

Signs of pneumonia, which were not verified by x-ray examination, developed over the left lower lobe. A total of 6 Gm. of sulfapyridine was given with good results. The child was discharged well after eight days of normal temperature. Two days later, at his home, an infection of the upper respiratory tract developed with nasal discharge and fever. After a week of elevation of temperature and failure to improve, the baby was again admitted to the hospital.

On admission the temperature was 102 F. The child appeared acutely ill and had a slight cough. There was dullness over the right lower lobe and a reddened left ear drum. A total of 8 Gm. of sulfapyridine was given in seven days. On the eleventh day after admission (four days after sulfapyridine had been stopped) the patient became fretful and began to vomit. The temperature rose to 102 F. and then dropped to normal within twenty-four hours. Vomiting continued for four days and then stopped; it was followed by diarrhea, which continued. There was a steady loss of weight, from 20½ pounds (9.3 Kg.)

5. From the pediatric service of Dr. H. S. Altman.

on admission to 18 pounds (8.2 Kg.) during the third week. The stools became less watery and more frequent.

During the fourth week after admission, signs of pneumonia again appeared over the right lower lobe. Before a report of the blood count could be obtained, the patient was given 1.25 Gm. of sulfapyridine. A blood count April 17 revealed 4,000 white blood cells, with 10 per cent polymorphonuclears. April 18 examination of the blood revealed hemoglobin 110 per cent, red cells 5,200,000, white cells 1,100, platelets 210,000 and reticulocytes less than 0.5 per cent. The differential count was nonsegmented polymorphonuclears 6 per cent, segmented neutrophils 2 per cent, lymphocytes 60 per cent, monocytes 30 per cent, basophils 1 per cent and myelocytes 1 per cent.

Aspiration of the sternal marrow revealed 60,000 nucleated cells and 88 megakaryocytes per cubic millimeter. The differential count was myeloblasts 1.4 per cent, myelocytes 71 per cent (fig. 1), eosinophilic myelocytes 1.8 per cent, nonsegmented neutrophils 1.2 per cent, segmented neutrophils 1.4 per cent, eosinophils 2.4 per cent, basophils 0.2 per cent, lymphocytes 3.2 per cent, hematogones 1.6 per cent, reticulum cells 0.2 per cent, megakaryocytes 0.2 per cent, erythroblasts 3.6 per cent and normoblasts 1.8 per cent.

The baby was given two blood transfusions and three injections of liver extract.

A blood count April 20 revealed 4,200 white cells. The differential count revealed nonsegmented neutrophils 4 per cent, segmented neutrophils 3 per cent, lymphocytes 37 per cent, monocytes 54 per cent (fig. 2) and myelocytes 2 per cent. The baby improved gradually and the rest of his stay in the hospital was uneventful.

CASE 2.—*Staphylococcus aureus osteomyelitis, treated continuously with sulfapyridine (95 Gm.), followed by lymphocytic granulocytopenia; fatal.*

H. W., a Negro boy aged 10 years, was admitted to the orthopedic service of Mount Sinai Hospital⁶ March 28, 1939, because of pain in the right shoulder of three days' duration. Three years previously, in an automobile accident, the patient suffered a fracture of the right clavicle. Two months prior

Fig. 1 (case 1).—Blood smear, monocytic granulocytopenia, magnification 1,000 diameters. Three monocytes and a plasma cell are shown at edge of smear.

to admission several furuncles appeared on his neck; these subsided without incision and drainage. Three days before admission he began to have pain in the right shoulder, which became worse. The temperature rose to 102.5 F.

The child appeared toxic, with rapid respirations and pulse; the temperature was 103.8 F. There were typical manifestations of osteomyelitis of the right humerus. An operation was

performed and the diagnosis was substantiated. The smear and culture at the time of operation yielded *Staphylococcus aureus*. For a few days following the operation the child continued to have fever. The temperature became normal on the fourth day. Treatment with sulfapyridine (1 Gm. every four hours) was started March 29, a total of 6 Gm. being administered

Fig. 2 (case 1).—Bone marrow, monocytic granulocytopenia, magnification 1,000 diameters. Three myelocytes with "toxic" granules, a myeloblast and a plasma cell are shown.

daily and continued until April 13. The patient received a total of 95 Gm.

On admission, examination of the blood revealed hemoglobin 95 per cent, white cells 16,700, nonsegmented neutrophils 8 per cent, segmented neutrophils 78 per cent, lymphocytes 6 per cent and monocytes 8 per cent. Several blood counts done before April 13 showed moderate leukocytosis and polynucleosis. However, April 14 examination of the blood revealed hemoglobin 69 per cent, red cells 4,250,000, white cells 3,400, platelets 180,000, nonsegmented neutrophils 10 per cent, segmented neutrophils 14 per cent, lymphocytes 71 per cent, monocytes 3 per cent and plasma cells 2 per cent. The temperature rose to 102 F. and remained elevated. The patient was given a transfusion immediately and later injections of pentnucleotide.

Examination of the blood April 17 revealed hemoglobin 84 per cent, red cells 5,100,000, white cells 700, platelets 240,000, and lymphocytes 100 per cent. On April 18 the blood showed a faint trace of sulfapyridine. Examination April 19 showed hemoglobin 72 per cent, red cells 4,960,000, white cells 300, platelets 160,000 and reticulocytes 1 per cent.

Aspiration of the sternal marrow revealed a total nucleated count of 25,000 cells (normal 200,000) and the following differential count: myelocytes 3.5 per cent (normal 30 per cent), segmented neutrophils 0.5 per cent (normal 20 per cent), lymphocytes 32 per cent (normal 15 per cent), hematogones

6. Dr. Seth Selig gave us permission to publish a report of this case.

3.5 per cent, plasma cells 1 per cent, reticulum cells 2 per cent, erythroblasts 1.5 per cent and normoblasts 56 per cent (normal 35 per cent).

The patient was given transfusions, but the white blood cells continued to decrease in number and the temperature reached 105 and 106 F. and remained there. His condition became worse and he died April 20. Permission for autopsy could not be obtained.

CASE 3.—*Hypoplastic anemia following intermittent use of sulfapyridine in a case of whooping cough and pneumonia; fatal.*

G. S., a Negro girl, aged 4 years, was admitted Jan. 25, 1939, to Willard Parker Hospital⁷ because of whooping cough. February 5 pneumonia developed, for which sulfapyridine was

Fig. 3 (case 3).—Bone marrow hypoplastic anemia; magnification 1,000 diameters. Reticulo-endothelial cells (vacuolated) and two normoblasts are shown.

given, 2 Gm. for the first dose and 0.5 Gm. every four hours, 3 Gm. a day being given up to February 13—a total of 20 Gm. The temperature dropped to normal February 7 but rose two days later.

February 15 signs of pneumonia again appeared and sulfapyridine was again given, 3 Gm. daily, without effect. The temperature dropped to normal February 19 but the drug was continued until February 21. *Pneumococcus serum type VI* was also given.

The temperature rose on February 21 and at that time the white count was 2,000, with 96 per cent lymphocytes. February 25 examination of the blood showed hemoglobin 64 per cent, red cells 3,400,000, white cells 1,100, platelets 105,000, lymphocytes 99 per cent and plasma cells 1 per cent. Aspiration of the sternal marrow revealed a total nucleated count of 33,800 per cubic millimeter and megakaryocytes 11 per cubic millimeter.

7. From the service of Dr. Jerome Kohn.

The differential count revealed myeloblasts 2.6 per cent, myelocytes 2.6 per cent, lymphocytes 37.3 per cent, hematogones 6 per cent, reticulum cells 5.3 per cent, megaloblasts 0.7 per cent, erythroblasts 10 per cent and normoblasts 35.5 per cent. The child's condition became worse, the temperature became elevated and, in spite of repeated transfusions, he continued to go down hill and died March 1.

A complete postmortem examination was obtained, the details of which will be reported later by Dr. Vera B. Dolgopol.

COMMENT

Sulfapyridine is a valuable drug in the treatment of pneumonia in adults and children.⁸ It is usually effective within two or three days.

In addition to the continuous nausea which usually follows the ingestion of sulfapyridine, dangerous toxic complications may arise, of which granulocytopenia and jaundice are the most important symptoms, especially in children. Strict precautions should therefore be exercised, and the blood picture, icterus index and bone marrow (obtained by sternal puncture) should be examined. A reduction in the number of white blood cells to 3,000 or 4,000 should be viewed as a danger signal. Administration of the drug should be stopped at this time and should certainly not be resumed until the number of white blood cells returns to normal. Its use beyond this period—especially if the temperature does not drop or if there is no improvement in the course of the disease—may in fact be regarded as ineffectual and possibly as dangerous. Sulfapyridine should be discontinued also if it induces anemia or if jaundice appears. The drug appears to be more dangerous if given over a long period or intermittently in various types of infection, including pneumonia in children.

It is important to remember that the toxic action may continue for several days after the drug has been discontinued. In case 2, for example, traces of sulfapyridine were still present in the blood five days after it had been administered. The necessity of following the trend of the blood picture and of making occasional observations of the bone marrow in all cases after prolonged use of the drug thus becomes apparent.

There is some variation of the effect of sulfapyridine on the bone marrow which is reflected in the blood picture. This resembles to a great extent the toxic action of neoarsphenamine.⁹ With both the bone marrow changes are rather definite and vary from a maturation arrest to a distinct, almost complete, suppression or hypoplasia of all the elements.

Case 1 is an example of only a moderate toxic action of sulfapyridine on the bone marrow inducing so-called maturation arrest. Although there is a marked decrease in the total nucleated count (60,000) there is a relative increase in myelocytes (71 per cent) with marked toxic granulation. The mature neutrophils are considerably diminished, to 2.6 per cent (normal 20 per cent). The blood picture showed a relative monocytosis up to 54 per cent. This is the type for which a good prognosis may be predicted; as has been previously reported, there is a high incidence of recovery in such cases.¹⁰ In case 2 the toxic action was apparently more marked with a severe depression of the myeloid elements, with relative

8. Barnett, Hartmann, Perley and Ruhoff.² Long.⁴

10. Rosenthal, Nathan, and Abel, H. A.: The Significance of Monocytes in Agranulocytosis (Leukopenic Infectious Monocytosis) Am. J. Clin. Path. 6: 205-230 (May) 1936.

increase in lymphocytes and normoblasts. The effect of the drug was still more marked in case 3, in which there was hypoplasia of all elements and an increase in the number of reticulo-endothelial cells (fig. 3).

It is important to follow the bone marrow as well as the blood picture in children who are receiving sulfapyridine for a prolonged or intermittent period. Attention should be paid to the cellular content, which, according to Vogel and Bassen,¹¹ should be about 200,000 per cubic millimeter. The finding of some diminution, especially when the content has dropped to less than 100,000, calls for caution in the further use of the drug.

Like sulfanilamide, sulfapyridine may exert a marked hemolytic action on the red blood cells of adults¹² and of children.¹³ Brahdy¹³ called our attention to the following case:

An Armenian boy aged 9 years was admitted to the Pediatric service of the Mount Vernon Hospital¹⁴ Feb. 20, 1939, with a history of fever, cough and pain in the chest of four days' duration. On admission signs of pneumonia (confirmed by x-ray examination) were found in the left upper lobe. The sputum showed a type I pneumococcus. The patient was given a total of 9 Gm. of sulfapyridine over a period of three days. A blood count February 21 showed hemoglobin 63 per cent, red cells 3,800,000, white cells 14,000, nonsegmented polymorphonuclears 14 per cent, segmented polymorphonuclears 68 per cent and lymphocytes 18 per cent. Jaundice was noted on the third afternoon and the drug was immediately stopped. The patient was given intravenous injections of dextrose, and the following day (February 24) the blood count revealed hemoglobin 20 per cent, red cells 1,400,000, white cells 22,600, nonsegmented polymorphonuclears 21 per cent, segmented polymorphonuclears 53 per cent, lymphocytes 24 per cent and monocytes 2 per cent. Following two transfusions the hemoglobin content rose to 43 per cent, with 1,750,000 red blood cells, 24,200 white blood cells and the following differential count: nonsegmented polymorphonuclears 17 per cent, segmented polymorphonuclears 78 per cent, lymphocytes 14 per cent and monocytes 1 per cent.

Again, as with sulfanilamide, the hemolytic reaction resulting from sulfapyridine, as exemplified in this case, occurs within a short time (about three days). This is in contradistinction to the development of granulocytopenia, which follows the prolonged or intermittent use of sulfanilamide or sulfapyridine.

The Special Function of the Skin.—It is gradually being recognized that the skin, far more than a mere protective covering of the body, is a separate and important organ, with physiological functions of its own that affect the body as a whole in a variety of ways. . . . That the skin has chemical functions of importance is apparent from investigations such as those of Folin, Trimble and Newman, who determined a rapid accumulation of sugar in the skin of animals when glucose was injected intravenously. The sugar concentration in the skin rapidly became almost equal to that in the blood. Trimble and Carey later, studying human skin from normal and diabetic subjects, found that elevation of sugar concentrations in the blood was accompanied by an absolute increase of the sugar in the skin, an increase far greater than that determinable in muscle tissue.—Zinsser, Hans; Enders, John F., and Fothergill, LeRoy D.: *Immunity Principles and Application in Medicine and Public Health*, New York, Macmillan Company, 1939.

Clinical Notes, Suggestions and New Instruments

PROSTATECTOMY AT THE AGE OF 110

J. BAYARD CLARK, M.D., NEW YORK

First of all, I wish to state the grounds of my belief as to this man's age, for it is here that the center of interest lies in this extraordinary case.

Aside from his own assertion and that of his family that he was born in the year 1827 in slavery in the state of Virginia, that he was not married until he was 40 and that his oldest son, if alive, would now be 70, I have made careful inquiries as to his supposed age from a number of reliable citizens in the town of Greenwich, Conn., where he became a resident after the Civil War.

A contractor for whom he worked on a building operation in 1900 or 1901 states that he was past 70 at that time. Another source of information is a remarkable old gentleman in his ninety-seventh year for whom the patient often worked and who knows him well. His belief is that he is well past 105, and a number of other trustworthy persons who seem to have known him most of their lives—two lawyers, four physicians and one clergyman over 80—place him as beyond 107 or 108, or even at the man's own estimate of 110. Further than this, for obvious reasons, it is hardly possible to authenticate his years.

It is, of course, a well known fact that many Negroes in slavery lived to be extremely old and beyond the age of this man. When one considers the possibility of their direct descent, in the early part of the last century, from a primitive African stock living in a natural way and untouched by the diseases of civilization, the fact of positive health and extreme longevity is not so strange. A cursory examination of the literature, however, revealed no report of a prostatectomy having been done in the case of any one reaching a hundred years of age.

This patient was admitted to the hospital May 19, 1938, suffering from acute urinary retention of four days' duration. He stated that there had been no previous difficulty or urinary disturbance. The abdomen was distended and the dome of the bladder reached to the umbilicus. The prostate was smooth, unevenly lobulated, elastic and about the size of a tangerine.

A soft catheter entered easily and gradual decompression was instituted.

His past history disclosed no pathologic condition. He maintained that he had never been ill but that some ten or twelve years before he was laid up for a few days because of a dislocated shoulder, which is still somewhat stiff.

As to his manner of living, he seems to have been moderate in all things except in the matter of paternity, having had twenty-two children, four of whom are still living. He eats sparingly of a diet of vegetables and milk. He smokes a pipe once a day. His work has been mainly outdoors and in later years that of road construction, the patient having had much experience in blasting operations.

Physical examination disclosed a thin, well muscled body. The skin had a healthy appearance. The teeth were mostly discolored stumps. The lungs were emphysematous. The heart

Fig. 1.—Six months after operation, still smiling.

sounds were somewhat weak and irregular, with no murmurs. The blood pressure was 140 systolic, 90 diastolic. Examination of the abdomen revealed a reducible inguinal hernia. The external genitalia were firm and surprisingly well developed.

Mentally he was alert, cheerful and responsive, having lost none of the lively sense of fun peculiar to his race. His eyesight was poor but his hearing was acute.

Examination of the urine and blood, including chemical analysis, gave essentially negative results.

Here was a peculiar picture of normality outside the usual experience, even with comparatively young patients in their seventies.

Taking it all together, it was difficult to resist the belief that he was a perfectly good surgical risk, so at the end of an uneventful week of catheter drainage it was decided to drain the bladder suprapubically. This was skilfully done by Dr. W. J. Washburn May 26 under local anesthesia, and a mushroom drainage tube was inserted. Save for a slight elevation of temperature the following day the patient suffered no reaction.

Suprapubic drainage was continued without incident until June 14, when prostatectomy was done.

Fig. 2.—Six months after operation, still walking.

Notwithstanding the conviction that the man was fully able to go through with the operation, there was still the lingering consciousness of stepping on untested ground which might give way when it was least expected. With this in mind, we reduced the operative procedure to its simplest form. Under light anesthesia with avertin with amylene hydrate the patient was brought sleeping to the operating room. The enucleation, which was a little more difficult than I had expected it to be, took between six and seven minutes. During this period the anesthesia was deepened with nitrous oxide gas. Two lobes, one a little larger than the other, were cleanly removed with very little bleeding. The prostatic bed was lightly packed with rib dam and the operation was over. The patient was returned to bed in excellent condition and given a clysis of 1,000 cc. of 5 per cent dextrose.

On waking the following morning after his operation he demanded a "square meal." On the third morning I found him propped up in bed joyfully puffing away at an ancient pipe. For five days his postoperative behavior was uneventful. Then something happened.

A temperature of 102.2 F. and a dry cough were reported. Examination disclosed dullness at the base of the right lung, and this was verified by the examinations made with a portable x-ray machine. There were no other physical signs or symptoms. Though he neither looked nor acted sick, precautions were taken against what might be. The next day his temperature reached 103 F. but he remained as cheerful as ever. There was no change in the picture except that the "dry cough" seemed to have vanished. Then of a sudden the gloom was lifted when a tender and moderately swollen right epididymis was discovered. One could contend with that at any age. The following day brought a level temperature and a subsiding epididymitis.

The moral of this case seems to be that perhaps the first hundred years of life are the worst after all.

Without further incident the suprapubic wound continued to close, and by July 1 he was passing urine by the urethra. The urine by this time was slightly cloudy with pus, but he showed

no symptoms of infection. By July 5 he was up and about the ward. July 10 he was discharged from the hospital.

The specimen weighed 30 Gm. The lobes were fibrous, containing glandular areas. There was a little scattered lymphocytic exudate. The diagnosis was benign hypertrophy of the prostate, with mild chronic prostatitis.

When at the end of July the patient reported at the hospital for a checkup he had no complaints and was enthusiastic about the free flow of urine. The urine was clear and the amount of residual urine was 40 cc. In September he was in his usual cheerful and healthy condition. The urine was clear and there was no residual urine. His visit, Jan. 12, 1939, showed no change from the previous examination. He laughed heartily when I gently chided him for coming out in freezing weather without an overcoat. This patient was still alive and very well June 26, 1939, one year after the operation.

HEMATOMA OF ABDOMINAL WALL OCCURRING IN A CASE OF WHOOPING COUGH

HERBERT E. BOWLES, M.D., HONOLULU, T. H.

Mrs. C., a widow aged 56, white, the mother of two healthy children now aged 22 and 26, had always been exceptionally well and for years had played forty-five holes of golf in one day twice a week. The patient had been taking care of two grandchildren who were suffering from typical pertussis. Three weeks before her present illness she contracted a classic case of whooping cough. Frequently paroxysms of severe coughing ensued.

Following one of these attacks during the night of May 12, 1936, the patient was seized with a sudden knife-like pain in the lower left quadrant of the abdomen and was admitted to the Queen's Hospital in Honolulu in profound shock. The pulse was rapid and thready and the entire body was bathed in a clammy sweat. In addition, respirations were shallow and sighing in type, and a tender mass was palpable in the left lower quadrant of the abdomen. On vaginal examination a tender tumor could be felt in the region of the left adnexa but slightly anterior to where adnexal tumors are usually found.

She was treated for shock by another physician, who gave her intravenous dextrose and saline solution and a blood transfusion. On admission the leukocytes numbered 9,300 with 66 per cent neutrophils. The following morning, shock had disappeared but she had a rigid, tender abdomen and the tumor mass was even more pronounced. The white cells now numbered 6,950. In addition, marked ecchymosis was noted in the left groin, pubes and vulva, around the anus and in the left buttock. The bluish discoloration had also extended up to and around the umbilicus. After several days with only bed rest the pain and rigidity grew less and she returned home. The tumor remained the same size and was very tender.

A vaginal examination two weeks after the onset of her illness revealed a large hypertrophic cervix, a hard, enlarged uterus (the size of a two months pregnancy) and a mass in the left adnexal region the size of a baseball, fixed, tender and protruding anteriorly. The ecchymosis showed evidences of clearing. Preoperative diagnosis was uncertain, but we believed that we were dealing with a left ovarian cyst twisted on its pedicle, or a hemorrhagic ovarian cyst. Pertussis vaccine was administered once a day for one week prior to operation. A general examination was negative except for a blood pressure of 190 systolic, 110 diastolic. The Wassermann reaction of the blood was negative.

Under nitrous oxide anesthesia a hypertrophic cystic cervix was amputated by Dr. G. C. Milnor. Following this the peritoneal cavity was explored through a midline subumbilical incision. All pelvic viscera appeared normal. The slightly enlarged fibrotic uterus was left alone. An elongated but otherwise normal appendix was removed. The examining hand then felt a swelling lying under the left rectus muscle and indenting the peritoneum markedly from above. The peritoneum was

closed and the lower portion of the left rectus sheath was then incised. Behind the muscle and arising from the left deep epigastric artery was a partly encapsulated semioorganized collection of black blood. Two hundred and fifty cc. of clots was evacuated, and the cavity was drained by a strip of rubber dam. No shredding or rupture of the rectus muscle was noted. Recovery was uneventful.

COMMENT

The case is presented as a matter of interest because of the likelihood of confounding it with various gynecologic conditions. So far as we can ascertain, hematoma of the abdominal wall occurring in whooping cough has not been previously reported, though Robertson¹ stated that it occurs in tetanus, typhus and miliary tuberculosis and that in elderly women obesity, pendulous abdomen and atheroma of the blood vessels undoubtedly play a part.

Most of the cases reported in the literature as spontaneous hematoma of the abdominal wall are not truly spontaneous, as careful reading of the history shows. This case cannot be called a spontaneous one since the accident immediately followed and was probably precipitated by the coughing spell. Other reports on the subject have been presented by Wohlgemuth,² Maxwell,³ Halperin,⁴ Hartmann,⁵ Culbertson⁶ and others. Lasch⁷ has shown that the hemorrhages in whooping cough are due to actual changes in vessel walls, which he thinks are of toxic-infectious origin. In our case atherosclerosis probably played a part.

SUMMARY

1. A case of hematoma from rupture of the left deep epigastric artery occurred in a woman aged 56 suffering from whooping cough. The rupture followed a paroxysm of coughing.

2. Most similar cases are not truly spontaneous, and search will usually reveal some form of associated violence.

TYMPANIC MEMBRANE DESTROYED BY JAPANESE BEETLE

MAX KIMBRIG, M.D., HUNTINGTON, N. Y.

C. L., a man aged 37, complained that two weeks previously a foreign body had entered his right ear and that he had not been able to hear well since.

Ear drops had been instilled within twenty-four hours by the nurse at his place of employment. At the expiration of two weeks he reported to his physician, Dr. Patiky, who referred him to me to remove what was found to be a Japanese beetle.

I had to amputate the wings first and then remove the body. The legs or biting equipment remained behind, stuck fast in the ear drum. They were removed after some difficulty. A perforation involving a very large part of the drum was present. There was a scanty odorless discharge. Hearing to all intents and purposes was normal. The patient gave no history of any previous ear trouble.

Since the Japanese beetle is herbivorous, it is difficult to understand his appetite for human ear drums. I have been unable to find in the literature any report of the destruction of an ear drum by a beetle which lives on plants.

Council on Pharmacy and Chemistry and Council on Foods

THE COUNCIL ON PHARMACY AND CHEMISTRY AND THE COUNCIL ON FOODS HAVE AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. THE DATE OF THE MEETING AT WHICH THE QUESTIONS WERE FIRST CONSIDERED WAS DEC. 9, 1938. THE REPORT, HOWEVER, REPRESENTS NOT ONLY ACTIONS TAKEN AT THE MEETING BUT OPINIONS ARRIVED AT FOLLOWING SUBSEQUENT DISCUSSION BY THE COUNCILS. THE REPORT, AS PUBLISHED, REPRESENTS THE COUNCILS' OPINIONS AS OF JULY 1939.

PAUL NICHOLAS LEECH, Secretary
COUNCIL ON PHARMACY AND CHEMISTRY
FRANKLIN C. BING, Secretary
COUNCIL ON FOODS

THE STATUS OF CERTAIN QUESTIONS CONCERNING VITAMINS BASED ON RECOMMENDATION OF THE COOPERATIVE COMMIT- TEE ON VITAMINS

The Cooperative Committee on Vitamins met at the Association headquarters Dec. 9, 1938. The following members of the Cooperative Committee were present: Dr. S. W. Clausen, Dr. H. N. Cole, Dr. G. R. Cowgill, Dr. Morris Fishbein, Dr. P. C. Jeans, Dr. Irvine McQuarrie, Dr. E. M. Nelson, Dr. L. J. Roberts, Dr. M. S. Rose, Dr. W. C. Rose, Dr. Torald Sollmann, Dr. F. C. Bing and Dr. P. N. Leech. In addition, the following members of the Council on Foods and the Council on Pharmacy and Chemistry were present: Dr. D. P. Barr, Dr. Joseph Brennemann, Dr. J. H. Brown, Dr. E. M. K. Geiling, Dr. E. E. Irons, Dr. H. B. Lewis, Dr. G. W. McCoy, Dr. J. S. McLester, Dr. R. M. Wilder. Also present as guests were Dr. T. G. Klumpp of the Food and Drug Administration, Dr. K. E. Miller of the Federal Trade Commission and Dr. T. D. Spies.

I. Questions Primarily Concerning the Council on Pharmacy and Chemistry

The Council on Pharmacy and Chemistry considered the matter of permissible claims for vitamins under the following classifications:

Permissible claims for vitamin A.

Permissible claims for riboflavin, thiamin chloride and nicotinic acid, including vitamin B complex.

Permissible claims for ascorbic (cevitamic) acid (including relation to arsenical eruptions).

Permissible claims for vitamin D and vitamin A and D preparations.

Based on this program the Council issued the following revised statement on permissible claims for vitamins and authorized its inclusion in N. N. R. for 1939:

VITAMINS

The investigations of nutrition that have been initiated since the second decade of the present century have afforded an entirely new outlook on many disorders, some of which have long been suspected to be of dietary origin. This is due to the scientific demonstration that in addition to the long recognized proximate principles—the proteins, carbohydrates and fats—which yield the energy requisite for life and activity and which, along with certain inorganic elements, form the structure of the tissues and the fluids of the organism, other factors also are essential for the preservation of bodily well being and physiologic function. They are at present commonly designated as vitamins.

The absence of any one of the vitamins from a diet which is satisfactory in other respects leads to the development of a syndrome which is called a "deficiency disease." These diseases may be as striking in their manifestations as are the direct result of underfeeding (caloric deficiency) or deprivation of essential inorganic elements such as iodine, iron, calcium or phosphorus. A striking illustration of a "deficiency disease" is presented by scurvy. This can be averted or effectively cured by the inclusion of foods which contain vitamin C (ascorbic acid) in the diet. It has been clearly established by convincing

experiments that the prophylactic or remedial agent—the antiscorbutic substance—is a definite chemical entity having the composition $C_6H_8O_6$. The vitamin is present in many articles used as food, such as green vegetables and fruits, yet lacking in others, such as the common cereals and grains. Ascorbic acid is readily destroyed by heat under certain conditions, notably in an alkaline medium and in the presence of oxygen. However, foods can be processed without serious loss of ascorbic acid if precautions are taken to exclude air and if the reaction of the food is not unfavorable for the preservation of the vitamin.

The foregoing illustration will suffice to indicate the characteristics of a vitamin—a substance essential for maintenance of normal metabolic functions, not identical with the more familiar nutrients, not synthesized in the human body, and therefore dependent on an exogenous supply, sometimes more labile than the foodstuffs proper and hence subject to deterioration, and distributed variously among the edible parts of animals and plants. A number of products having the properties of vitamins have been isolated or synthesized.

For convenience the designations vitamins A, B, C and D, and so on have arisen. Scurvy, beriberi, rickets, pellagra and xerophthalmia have been attributed with considerable experimental certainty to the lack of specific vitamins; the protective or curative substances are accordingly sometimes spoken of as the antiscorbutic vitamin (C), the antirachitic vitamin (D), the antineuritic vitamin (B_1), the antixerophthalmic vitamin (A), and so on. Detailed accounts of the physiology of the vitamins can now be found in the newest textbooks on physiologic chemistry and nutrition. The problems raised thereby are the subject of active discussion and extensive investigation, so that with respect to many features only tentative conclusions should be announced at this time.

While some helpful chemical and physical methods for determining the quantity of vitamins present in a given product are now available, for conclusive evidence we must rely on biologic assays. To facilitate such assays and to make for uniform expression of vitamin content, the Health Organization of the League of Nations has sponsored the preparation and distribution of standards for vitamins A, B_1 , C and D. The international unit for each of these vitamins is defined in terms of the biologic activity of a specific quantity of the respective standard. The U. S. P. XI units for vitamins A, B_1 and D are identical in value with the international units.

Although considerable evidence bearing on the subject has accumulated the requirements for vitamins A, B_1 , C and D for either infants or adults have not been established except within rather wide limits. Apparently there is no reason why a properly selected diet should not afford an adequate supply of the requisite vitamins. Furthermore, with the exception of pellagra and a possible vitamin B_1 deficiency there is no evidence of a noteworthy prevalence in this country of conditions in adults that might properly be ascribed to a lack of one or more vitamins. However, under circumstances bringing about a highly restricted dietary regimen and leading to "one-sided" diets a relative shortage of some of the vitamins at times arises. In many such instances the situation can be properly corrected by prescription of appropriate foods. Occasionally, and particularly with infants, a corrective result may be more effectively and more speedily secured by the administration of the vitamin itself or products especially rich in the desired vitamin; for example, cod liver oil as a dietary adjunct in the prevention or treatment of rickets, and orange juice or crystalline ascorbic acid in the relief of scurvy.

The chief justification for the recognition of special vitamin-bearing products at present applies to unusual concentrations of the desired potent principle that they may represent or to exceptionally desirable dosage forms. These considerations, which may be modified by the progress of research, have served as criteria in the selection of products offered for inclusion in N. N. R. as products rich in specific vitamins at present recognized to have demonstrable value in clinical practice or human nutrition; or as pure substances such as carotene, which is a precursor of vitamin A, ascorbic acid (crystalline vitamin C), or thiamin chloride (crystalline vitamin B_1).

The Council considered the matter of mixed vitamin therapy and decided that for the present there seems to be no more logical basis for including all or a number of vitamins in one

preparation than there is for combining a number of other known dietary essentials in any one pharmaceutical product. Since vitamins A and D occur together in nature, and on the basis of the long clinical experience with cod liver oil the Council accepts products containing these two vitamins. The Council will consider for acceptance vitamin concentrates of the required potency made from a single natural product which may contain more than one of the known vitamins.

VITAMIN A

The term "vitamin A" has been applied to any one of several substances or to a mixture of them producing a certain demonstrable specific physiologic effect. It seems to have been definitely established that there are at least five substances which can produce to some degree this characteristic response in the animal body. These are vitamin A itself, alpha, beta and gamma carotene and cryptoxanthin. The last four of these, the precursors of vitamin A, are produced in the plant kingdom, and ingestion of these substances by most animals results in varying degree (depending on the species of animal and the precursor fed) in the formation of a compound having the empiric formula $C_{40}H_{56}OH$ and to which no other name than vitamin A has been given. The extent to which the different precursors of vitamin A can be converted to vitamin A by different species of animals has not been definitely established. The exact function of vitamin A has not been established, but the pathologic picture which results from varying degrees of deficiency has been the subject of extensive investigation.

The claims recognized under vitamin A shall be recognized under the precursors of vitamin A only under conditions specified elsewhere under Carotene.

Allowable Claims.—1. Evidence for the existence of vitamin A and its role in human nutrition is based on the fact that a characteristic eye disease, usually called xerophthalmia, results from a deficiency of this vitamin.

2. It is generally agreed that the first symptom or at least one of the first clinical symptoms of vitamin A deficiency is night-blindness, or nyctalopia. For this type of night blindness vitamin A is a specific. Cases of nyctalopia exist which do not respond to treatment with vitamin A. These may be due to congenital defects or to other diseases than avitaminosis A. In view of present knowledge, the claim is not acceptable that the administration of vitamin A to drivers of automobiles will diminish the chance of accident from driving at night.

3. Vitamin A is reported to be effective in the treatment of certain types of hyperkeratosis of the skin of persons suffering from severe deficiency of vitamin A.

4. Present indications are that vitamin A is an aid toward the establishing of resistance of the body to infections in general only when there has been a decrease of body reserves of the vitamin and the ingestion of vitamin A is inadequate. It has not been shown to be specific in the prevention of colds, influenza and such infections, nor has it been demonstrated that ingestion of vitamin A far in excess of that necessary for normal body function and readily obtained from a properly selected diet is an aid in preventing various types of infections.

5. A deficiency of vitamin A results in a retardation of growth when body stores of the vitamin have been sufficiently depleted, but it must be borne in mind that vitamin A is no more important in contributing to normal growth than any one of the other vitamins, the essential mineral elements or amino acids. Statements conveying the impression that vitamin A is more important in promoting growth than other food essentials are therefore considered misleading and objectionable.

6. There is at the present time inadequate evidence to warrant the claim that the ingestion of sufficient vitamin A will prevent the formation of renal calculi in man or that it is useful in the treatment of hyperthyroidism, anemia, degenerative conditions of the nervous system, sunburn or ulcerative conditions of the skin.

THE VITAMIN B COMPLEX

The term Vitamin B Complex is applied to a group of substances which have been shown to be constituents of what was formerly called vitamin B. The exact number of these con-

stituents is not known at present but the following have been mentioned in recent discussions of the subject:

Thiamin (vitamin B₁) or Thiamin Chloride (vitamin B₁ hydrochloride), the antiberiberi vitamin which prevents beriberi in man and polyneuritis in animals.

Riboflavin, a compound necessary for growth in chicks and rats, and for the prevention of cataract in rats. It is a component of an oxidation-reduction system of living cells.

Nicotinic Acid (amide), (P-P Factor), a nutritional factor effective in the treatment of human pellagra and curative of blacktongue in dogs.

Filtrate Factor, a factor for the prevention of a nutritional dermatosis in chicks.

Vitamin B₂, a factor necessary for rapid gains in weight and normal nutrition of pigeons.

Vitamin B₃, a factor for the prevention of a specific paralysis in rats and chicks.

Vitamin B₆, a factor necessary for weight maintenance of pigeons.

Vitamin B₉, or, Vitamin H, a factor for the prevention of a nutritional dermatosis in rats.

Factor W, a factor necessary for growth of rats.

The chemical nature of thiamin, riboflavin, nicotinic acid (amide) and vitamin B₆ is known. There is biologic evidence, some convincing and some rather vague, for the other factors named. Only thiamin, nicotinic acid (amide) riboflavin and vitamin B₆ have thus far been definitely shown to be necessary in human nutrition and to be of therapeutic value in human disease.

The use of the term vitamin G has led to considerable confusion. This term should not be used to designate the pellagra-preventive factor. It has been demonstrated that vitamin G as determined by the Bourquin-Sherman procedure is a measure of riboflavin. Since this is the most widely accepted procedure for determining riboflavin content, the Council will for the present recognize claims for vitamin G content on the basis of Bourquin-Sherman units in natural products or concentrates named from them. However, it seems preferable to modify the Bourquin-Sherman technic to the extent of using pure riboflavin as a reference standard so that potency can be expressed in micrograms of riboflavin. There appears to be no necessity of labeling pure preparations of riboflavin to show vitamin G units.

While it has been shown that riboflavin is necessary for the normal nutrition of certain species and has a wide distribution in living cells, there is only limited evidence bearing directly on its role in human nutrition. Recent reports indicate that this substance as well as vitamin B₆ may be of value in the prevention and cure of some of the symptoms frequently associated with pellagra.

THIAMIN (THIAMIN CHLORIDE)

Thiamin is recognized as being of fundamental importance in connection with the disease beriberi. The pure compound was first isolated in 1927. Since that time its chemical constitution has been established and it is now being manufactured synthetically. It is usually prepared as the hydrochloride, thiamin chloride, which has the formula C₁₂H₁₇O₄N₄SCl₂·HCl.

During the past year the International Conference on Vitamin Standardization adopted crystalline vitamin B₁ hydrochloride as the standard for this vitamin and defined the unit as the biologic activity of 3 micrograms of this standard.

Allowable Claims (Thiamin).—1. Thiamin is of value in correcting and preventing beriberi.

The consensus of the students of beriberi is that this disease is due primarily to an insufficient supply of thiamin. There are conditions which probably could be designated as "latent beriberi"; it does not seem wise at this time to attempt the formation of a definite statement covering such conditions other than that presented in item 7.

2. Thiamin may be cited as of value in correcting and preventing anorexia of dietary origin in certain cases.

There are many causes of anorexia, some referable to infections and the reactions thereto, others to organic disorders, and still others related to faulty diet. Where there is no rather obvious cause of anorexia in question, other than a possible dietary one, it is permissible to claim that

thiamin may be of therapeutic value when the condition to be treated is due to a deficiency of that vitamin.

3. Thiamin is of value in securing optimal growth of infants and children.

Citations in the literature support the claim that a sub-optimal supply of thiamin results in limitation of growth.

4. The therapeutic use of thiamin chloride may be recommended when there are specific conditions indicating interference with proper assimilation of the vitamin from the food.

The present status of research on the clinical use of thiamin for specific diseases other than beriberi and for infant feeding is such that *definite* claims for therapeutic value in relation to such diseases cannot be recognized. Its use may be indicated, however, in such restricted conditions as pernicious vomiting of pregnancy, tube feedings through a jejunal fistula, and the like, because the foregoing permitted statement applies to such conditions and gives an intelligent basis for such therapy.

5. Claims for concentrates of thiamin offered for clinical use should state the potency in terms of the international unit. The term "concentrate" or a synonym will not be recognized if the product does not exceed a potency of 25 international units per gram (or per cubic centimeter), or if it is a natural product which may have been subjected to a process of dehydration.

6. In connection with medicinal foods acceptable for N. N. R., the claim that a food is valuable because of its thiamin content may be made only if it provides in the quantity of food consumed daily at least 200 units of thiamin.

Any food preparation having less than such an amount cannot be regarded as a noteworthy medicinal source of the vitamin. In the light of present knowledge the daily requirement for thiamin appears to be not less than 50 units (international) for the infant and 200 units (international) for the adult.

7. While it has not been established that thiamin deficiency is the sole cause of conditions described as alcoholic neuritis, the neuritis of pregnancy and the neuritis of pellagra, there is evidence of the value of this vitamin in the treatment of these conditions. Vague representations with respect to the value of thiamin in the treatment of other types of neuritis are not permissible.

8. It appears that there is an increased requirement for thiamin when there is greatly augmented metabolism such as occurs in febrile conditions, hyperthyroidism or vigorous muscular activity.

NICOTINIC ACID AND NICOTINIC ACID AMIDE

When dogs are fed a pellagra-producing diet they develop a disease known as "blacktongue," which is cured by the administration of either nicotinic acid or nicotinic acid amide. For a number of years canine blacktongue has been regarded as an analogue of human pellagra. Because of the apparent relationship of the two diseases the Council voted in 1938 to accept nicotinic acid and nicotinic acid amide "for purposes of standardization and clinical experimentation." Sufficient evidence has now been accumulated to demonstrate the usefulness of these drugs in the treatment of pellagra.

Allowable Claims (Nicotinic Acid).—1. Nicotinic acid (amide) is recognized as a specific only in the treatment of acute pellagra in relapse. Its administration in appropriate doses leads to the disappearance of alimentary, dermal and other lesions characteristic of the disease, to a return to normal of the porphyrin and porphyrin-like pigments of the urine, and to a profound improvement in the mental symptoms when the latter are the result of an inadequate intake of nicotinic acid (amide). Nicotinic acid is without influence on the polyneuritis and certain other symptoms frequently observed in pellagrous patients. In such cases it may be necessary to insure the presence in the diet of foods rich in vitamin B₆ or to administer thiamin chloride. Riboflavin and vitamin B₆ may also be required for the relief of other symptoms not influenced by nicotinic acid or thiamin chloride.

2. Available evidence does not warrant the use of nicotinic acid (amide), riboflavin or vitamin B₆ for prophylaxis.

lactic purposes or the suggestion that these substances be employed as a supplement to the ordinary diet. The protective dose, and the amount which should be present in a well balanced ration, are unknown.

ASCORBIC ACID (Cevitamic Acid)

There is ample experimental and clinical evidence to show that ascorbic acid in optimal amounts is an essential dietary constituent. Suboptimal amounts result in the development of clinical and pathologic phenomena to which the descriptive term scurvy has been applied.

The chemical nature of the formerly unidentified essential food substance has been discovered. Its empirical formula is $C_6H_8O_6$, ascorbic acid (cevitamic acid), which has been prepared in commercial quantities both from natural sources and through synthesis.

Allowable Claims (Ascorbic Acid).—1. Ascorbic acid is acceptable for the correction and prevention of scurvy. This effect has been established experimentally and by clinical investigation.

2. Definite claims for the therapeutic value of ascorbic acid should be permitted only in relation to scurvy until further clinical or experimental evidence has substantiated its usefulness in other states.

3. It may be permissible under certain conditions to refer to the therapeutic value of ascorbic acid in early and latent scurvy. Convincing clinical evidence has established that this state does occur. It would be well to emphasize the fact that the diagnosis rests, however, on the basis of roentgenologic evidences in the long bones, and possibly failure to excrete an optimal amount of ascorbic acid in the urine.

4. Dental caries, pyorrhea, certain gum infections, anorexia, anemia, undernutrition and infection alone are not in themselves sufficient indications of ascorbic acid deficiency but according to experimental and clinical investigation they may be concomitant signs of ascorbic acid deficiency. Therefore, it is permissible to accept the claim for the therapeutic value of ascorbic acid in these symptomatic conditions *only when* it is definitely stated that they are the consequences of a deficiency or suboptimal amount of ascorbic acid or when there is a pathologic interference with assimilation of the amount necessary for the preservation of health.

5. Unless more convincing evidence is present than is now available, no claim referable to the anti-infective effect of ascorbic acid will be recognized. Secondary infections are characteristic of disturbances of nutrition, particularly in all vitamin deficiency diseases. It has not been established that ascorbic acid has a therapeutic effect which directly influences associated secondary infections in scurvy.

6. Because ascorbic acid is a dietary essential, its administration in concentrated form is of value in conditions in which difficulty in introducing orally or utilizing ordinary foods in the usual way is encountered. Ascorbic acid is accepted as an essential dietary constituent in infant feeding but it should not be accepted for use in the treatment of diseases except according to the conditions mentioned. It is generally administered in the form of an ascorbic acid carrying juice. It may be administered parenterally in concentrated form as sodium ascorbate when persistent vomiting, diarrhea or other conditions prevent the utilization of proper amounts taken orally.

7. Ascorbic acid offered for clinical use must state the potency in terms of the international unit. The international unit for ascorbic acid, which was formerly defined as the vitamin C activity of 0.1 cc. of lemon juice, is now defined as the ascorbic acid activity of 0.05 mg. of ascorbic acid. This is the quantity of ascorbic acid usually found in 0.1 cc. of lemon juice.

8. In the opinion of the Cooperative Committee on Vitamins, adopted by the Council, the claim that a food is valuable because of its ascorbic acid content should be permitted only if it provides a daily intake of at least 250 international units of ascorbic acid.

9. A reasonable general statement regarding allowable claims for ascorbic acid would be as follows:

An optimal amount of ascorbic acid should be supplied at all ages for its therapeutic value in preventing the development of acute or latent scurvy.

Claims for the therapeutic value of ascorbic acid may be accepted when the agent is described as a corrective measure for scurvy due to a demonstrable absence or a suboptimal quantity in the diet, or in cases in which it is definitely known that there is interference with the absorption of an optimal amount.

Advertising of ascorbic acid for such symptoms as failure to gain in weight or stoppage of growth, anorexia, anemia, infections, symptoms referable to the central nervous system or hemorrhagic conditions cannot be accepted unless it is definitely stated that the symptoms are referable to a demonstrable deficiency of ascorbic acid.

The ascorbic acid equivalent or potency in terms of international units should be stated in all dosage claims for ascorbic acid. Ascorbic acid is easily decomposed in presence of certain other substances; therefore, care should be exercised against administering it (or orange juice) in mixtures, or by any procedure which renders it ineffective.

VITAMIN D

The term "vitamin D" is applied to one or more substances which function in the proper utilization of calcium and phosphorus. Vitamin D has been produced in crystalline form as one of the products of ultraviolet irradiation of ergosterol and shown to be a sterol having the formula $C_{28}H_{44}O$. Two forms of naturally occurring vitamin D have now been isolated and one of these forms is identical with the vitamin D produced by the activation of ergosterol.

Some reports have appeared claiming clinical improvement in chronic arthritis and in certain allergic disorders as a result of the use of massive doses of vitamin D. Critical examination of these reports reveals little to warrant the belief that the clinical effects claimed are specific. There is suggestive clinical evidence that the use of massive doses of vitamin D may cause improvement in some cases of psoriasis, but the effect is not yet well enough established to justify a claim for such use. The Council believes that further studies should be conducted, but because of the possible toxic effects of large doses of vitamin D it is necessary that such studies should be made only in clinics where close supervision is possible. The Council also holds there is not sufficient evidence to warrant the acceptance of viosterol preparations of high potency for use in the treatment of arthritis.

Allowable Claims (Vitamin D).—1. Vitamin D is recognized as a specific in the treatment of infantile rickets, spasmophilia (infantile tetany) and osteomalacia, diseases which are manifestations of abnormal calcium and phosphorus metabolism. Vitamin D is valuable in the prevention as well as in the curative treatment of these diseases. Complications such as renal insufficiency or glandular malfunction may preclude normal response to vitamin D therapy. During acute infections, especially of the gastrointestinal tract, vitamin D may prove ineffective because poorly absorbed.

2. Direct exposure of the skin to ultraviolet rays from the sun or from artificial sources results in the formation of vitamin D within the organism but the Council cannot recognize statements or implications that vitamin D has all beneficial effects of exposure to sunshine.

3. There is clinical evidence to justify the statement that vitamin D plays an important role in tooth formation and maintenance of normal tooth structure, but there is no warrant for the claim that adequate vitamin D intake will insure normal tooth structure or that adequate vitamin D intake will prevent dental caries.

4. Animal experimentation has shown that correction of an inadequate intake of vitamin D results in the more economical utilization of calcium and phosphorus and also that the undesirable effects of improper ratios of calcium and phosphorus in the diet can largely be overcome by normal intake of vitamin D. The importance of these observations in their application to man is not entirely apparent because

of the lack of adequate clinical evidence showing the availability of different forms of calcium and phosphorus, but it may be stated that vitamin D has a favorable influence on calcium and phosphorus metabolism.

5. The vitamin D requirement appears to be greatest during the period of infancy. Beyond the age of infancy the exact vitamin D requirement of man under any specified conditions is not known but it appears that the requirement during pregnancy and lactation is increased.

6. Clinical evidence does not warrant the claim that massive doses of vitamin D are of benefit in chronic arthritis, in allergic disorders or in psoriasis.

MISUSE OF TERM VITAMIN F FOR LINOLEIC OR LIOLENIC ACIDS

In previous statements it has been pointed out that the use of the term vitamin F for linoleic or linolenic acids is not warranted. On recommendation of the Committee on Vitamin Nomenclature of the American Society of Biological Chemists, that organization and the American Institute of Nutrition have adopted the following statement:

"The term 'Vitamin F' has been used in various ways in the past but recently has come into widespread use in promoting the sale of linseed oil and products alleged to contain so-called fatty acids. A group of biochemists interested in fat metabolism gave consideration to this matter during our last meeting. They informed this committee of the recommendation that the term vitamin F should not be used in referring to linoleic or linolenic acids, or so-called essential fatty acids. Your committee is in accord with these views, and it is recommended that the term vitamin F should not be used in referring to linoleic or linolenic acids, or any fatty acids or mixtures of fatty acids."

On recommendation of the Cooperative Committee on Vitamins, the Council on Pharmacy and Chemistry voted to endorse the action of the American Society of Biological Chemists and the American Institute of Nutrition.

VITAMIN K

The Cooperative Committee recommended to the Council that reports be made on the substance called vitamin K (one report was published in *THE JOURNAL* [Vitamin K: Its Properties, Distribution and Clinical Importance], April 15, 1939, page 1457).

POSSIBILITY OF REDUCING NUMBER OF TYPES OF VITAMIN A AND D PREPARATIONS FOR DIFFERENT CLASSES OF MANUFACTURED PRODUCTS

In following the action of the Council on dosages for vitamin A and D preparations it has become apparent that there are a great many types of preparations, making it almost a hopeless task for a physician to use these products to the best advantage, so far as dosage and potency are concerned. The suggestion was made to the Cooperative Committee that the number of types of these preparations be reduced by prescribing the potency for each type of product that might be accepted. There are very few preparations of the same type that have the same potency, whether it is cod liver oil, which ranges from 850 to 2,000 units of vitamin A and 85 to 250 units of vitamin D, or another oil of various constituents or the various concentrate preparations.

The committee recommended to the Council therefore that it consider in the near future the question of limiting arbitrarily the number of preparations as to strengths of vitamins A and D, and that the referees in charge of these products be instructed to bring in specific recommendations as to the types and potencies to be designated.

The proposal of the Pharmacopoeia to designate three different types of vitamin containing oils was discussed. Criticisms were made of this proposal and it was decided that the subject of the nomenclature of these preparations should be brought to the attention of the U. S. P. Revision Committee in order that there might not be conflicts between the rules of the Council and the proposed names that might be adopted by the U. S. P. Revision Committee.

VITAMIN NOMENCLATURE

The question of vitamin nomenclature was again discussed. The members of the Cooperative Committee and of the Council have expressed the hope that those who discover in pure form the active principle of the vitamin or who discover new vitamins will follow some procedure whereby objectionable types of names will not be created. As has been pointed out previously, names which are therapeutically indicative or which use numbers, or the names of persons or towns, are not conducive to scientific nomenclature. The Council on Pharmacy and Chemistry has established contact with the Nomenclature Committee of the American Society of Biologic Chemists. This body has indicated willingness to consider proposed names in cooperation with the Council. The Council must insist that the names be not therapeutically suggestive.

II. Questions Primarily Concerning the Council on Foods

FORTIFICATION OF FOODS WITH VITAMINS

The idea of fortifying foods with dietary essentials is not new but had its beginning with the introduction of iodized salt. Later the question of the fortification of foods with vitamin D was brought up when the possibility of irradiation with ultraviolet or the addition of fish liver oil concentrates was developed commercially and the need for vitamin D in the prophylaxis of rickets was made evident. On the basis of evidence available, the Council on Foods decided that of the common foods only milk should be accepted when fortified with vitamin D. Other items such as chewing gum, beer, cake flour, candy, ice cream and sausage represent specific instances of indiscriminate fortification not recognized by the Council as being in the interest of public health.

As a result of its experience, the Council on Foods in 1936 adopted a statement of general policy regarding this question. It was then decided that general and indiscriminate fortification of foods with vitamins (as well as minerals) should be discouraged; the Council is aware, of course, that when a need is recognized for a certain dietary essential, and a food is shown to be suitable as a vehicle for that vitamin or mineral, fortification might be justified. New evidence and new problems would necessitate a reconsideration of the problems and policies.

Among the recent questions presented to the Council on Foods, reviewed by the Cooperative Committee, have been the following:

(a) Is oleomargarine fortified with vitamin A acceptable? This already has been decided in the affirmative because oleomargarine is used as an alternate for butter and it is desirable to provide in other food fats the vitamin A which is lost from the diet by the use of food fats lacking this vitamin.

(b) Should the fortification of flavored milk drinks with vitamin D be recognized? The Council has decided that products which are used like milk and which provide the calcium and phosphorus of milk in suitable amounts may well be fortified with vitamin D.

(c) What attitude should be taken toward food products fortified with preparations obtained from fish liver oils which provide both vitamins A and D? Some oleomargarines to which vitamin A has been added also supply a considerable amount of vitamin D, because both vitamins are present in fish liver oils. Similarly, some milk preparations to which concentrates of cod liver oil have been added as a source of vitamin D also supply additional vitamin A. The Committee agreed that no objection be taken to the concurrent presence of either vitamins A or D when preparations containing both vitamins are used for purposes of fortification with one, but the claims should be restricted to those supported by suitable evidence.

(d) The Council believes that fortification of cereal products with vitamin D is inadvisable because cereals ordinarily do not contain vitamin D and because this vitamin is of no value unless calcium salts also are provided. There are many phases of this question which require consideration and a more detailed report will be prepared on this subject. The Cooperative Committee reaffirmed the policy of the Council.

(e) What policy should be adopted in regard to the addition of vitamin B₁ to cereal products? The Council has taken no objection to the addition to cereal products of wheat germ or

dried yeast as sources of the vitamin B complex. Various considerations render unpractical the addition of wheat germ or dried yeast to many foods. Synthetic thiamin chloride is now available commercially and it has been suggested that milled cereal products might well have the vitamin B₁ content restored to the B₁ value of whole grain. This question involves many important points which need separate discussion.

(f) Ordinarily yeast is considered to be an important source of vitamin B₁ and vitamin G as well as other factors usually designated by the term "vitamin B complex." Fresh yeast is ordinarily not as rich a source of vitamin B₁ and vitamin G as has been supposed. The growing of yeast on culture mediums which will enhance the natural vitamin potency of the yeast, as well as other steps designed to accomplish the same end, represents a distinct advantage.

(g) The question has been raised whether it would be desirable to add vitamin B₁ to soda pop and whisky. The Council is opposed to such fortification because these preparations are not desirable in any nutritional program and because other considerations should make it self evident that fortification of alcoholic beverages cannot receive the approbation of the Council.

(h) The opinion of the Council regarding the addition of vitamin B₁ to sugars has been requested. There naturally are numerous questions which enter into any decision that might be made on this problem. A decision was withheld pending the accumulation of more data.

(i) Canned tomato juice usually contains about 40 per cent of the vitamin C content of fresh orange juice. One firm has asked the Council's opinion about the addition of vitamin C to canned tomato juice in order to increase the antiscorbutic potency to that of fresh orange juice. It was decided by the Cooperative Committee that the addition of vitamin C to canned tomato juice would serve no useful purpose because ordinary tomato juice when properly packed is a rich source of vitamin C and because there is no evidence of a need for a fortified product by the general public. The Council adopted the policy of not accepting at present canned tomato juice when fortified with vitamin C.

In discussing the subject there were many points to which consideration was given by the Cooperative Committee. The fortification of foods should make it easier for people generally to obtain an optimal diet. The vitamins of known significance in human nutrition are vitamins A, B₁ (thiamin chloride), C (ascorbic acid), D, G (riboflavin), nicotinic acid and possibly vitamin B₆. For these essentials the requirements are still under investigation and certainly the optimal quantities of any are far from being established. There are, however, certain more or less empirical rules that have been adopted as guides for the selection of diets which are considered suitable in the light of existing knowledge. It is becoming apparent that for various reasons, especially lack of knowledge, the people of the United States do not select foods to furnish the best possible diets for the money invested. More data are needed to determine actual intakes, but even with the data now available it is possible to point to some general tendencies toward deficiency in the national dietary. There is increasing evidence, for example, that more vitamin B₁ in the diet may be desirable. Although recent information shows that some meats, a hitherto unexpected source, provide considerable amounts of vitamin B₁, it also has been shown that many whole grain products of the ready-to-eat cereal class have lost much of the vitamin B₁ which was present in the original form, owing to the heating to which the products are subjected. There may be a need for more vitamin B₁ in the diet, but there is also a need for reexamination of available sources and greater emphasis in educational programs on the need for this vitamin. In any case present progress in teaching the applications of nutritional research to the public is slow because of few agencies devoted to this kind of education.

There is evidence that in certain parts of the country there is, in general, a low intake of other members of the vitamin B complex, particularly nicotinic acid and riboflavin. It is not established that marked deficiency of vitamin A and vitamin C in the diet occurs, but it is considered that the optimal diet requires more vitamin A and vitamin C than the average diet provides.

The fortification of foods with vitamins (or minerals) should not be viewed as a substitute for educational programs. Rather it should be considered that fortified foods simply afford an additional source of important dietary essentials needed for the attainment of optimal nutrition. Further, if vitamin A is to be made available in the form of fortified foods, such fortification may well be limited to food fats. Similarly, if vitamin B₁ is to be added to foods, those products which naturally furnish this vitamin but have lost it in processing should be the foods selected for its restoration. The addition of vitamin B₁ to milled cereal products thus appears to be justifiable.

It was brought out that it is important to keep the rules for dietary programs as simple as possible. If a great variety of vitamin D fortified foods are offered, for example, to the public, there is quite likely to be confusion in the mind of the mother trying to give her children the advantages of the modern knowledge of nutrition. This is an additional reason for recognition of milk alone of ordinary foods for fortification with vitamin D.

It was emphasized also that dietary deficiencies, while not limited to any group, are most likely to appear among people with low incomes. Any campaign for the nutritional improvement of foods should give careful consideration to the costs involved, because a higher cost of the final product may defeat the purpose of the fortification.

It was brought out that the fortification of foods cannot be considered without study of laws and regulations pertaining to foods. Thus, many municipalities have regulations prohibiting the addition of foreign substances to milk. In some localities this regulation, which obviously was formulated with a desire to protect the public, has been used to prohibit the addition of vitamin D preparations to milk. This action, in the opinion of the Council on Foods, is not in harmony with the modern knowledge of nutrition.

Another case in point is the prohibition by the Bureau of Animal Industry of the addition of oils containing vitamin A to oleomargarines made from animal fats. In this country animal products for human consumption are manufactured in establishments which are inspected by the Bureau of Animal Industry of the United States Department of Agriculture. That bureau has ruled that vitamin preparations come under the class of possibly harmful and deleterious substances and cannot be permitted on the premises of the manufacturing establishments. There is today no oleomargarine made from animal fats in the United States which contains added vitamin A, and under the present regrettable decision there can be none. Oleomargarines made from vegetable fats and oils may contain added vitamin A in the form of a small amount of a fish liver oil because these products do not come under the jurisdiction of the Bureau of Animal Industry. It may be mentioned that in some European countries no oleomargarine may be sold unless it is fortified with vitamin A and also with vitamin D.

In the opinion of the Council, legislation and regulations pertaining to foods should be enacted with reference to the best interest of the public. Fortification should not be prohibited but it should be controlled.

It was brought out that the policies regarding fortification of foods should be established with careful consideration of the known facts regarding the interrelationships of dietary essentials in the food product during storage and during digestion and metabolism. Thus, the addition of iron in large quantities may result in the catalytic destruction by oxidation of some of the vitamin values of foods. The addition of large quantities of phosphate may result in the loss of iron and calcium because of the formation in the digestive tract of insoluble phosphates of these minerals. It is also possible that some factors may have a harmful effect when too much is taken. Before nicotinic acid could be added to foods as part of the effort to prevent the incidence of pellagra, it would be necessary to know more about requirements and the behavior of this vitamin when added to foods. More information is needed about the interrelationship of vitamins and minerals in metabolism. These questions are amenable to experimental proof. There should be evidence of the merits of any fortified

food product before it is marketed. Fortification of foods must be guided by nutritional principles rather than the desire for developing new advertising claims.

On the basis of the foregoing discussion, the Cooperative Committee adopted the following resolutions regarding future policies for consideration by the Council on Foods:

I. *Resolved*, That the restorative addition of vitamins or minerals, in such amounts as will raise the vitamin or mineral contents of foods to recognized high natural levels, be encouraged; with the provision that such additions are to be limited to vitamins or minerals for which a wider distribution is considered to be in the interest of the public health, and with the further provision that the additions are made only to foods which naturally are principal sources of supply of the vitamins or minerals in question.

II. *Resolved*, That the indiscriminate fortification of foods with vitamins or minerals be discouraged. By such fortification is meant either the addition of any vitamin or mineral to foods which naturally are not principal sources of supply of the substance added, or the addition to a food of an amount of any vitamin or mineral which is larger than that naturally contained in some food of its class. The following exceptions will be recognized: 1. The addition of vitamin D to milk to an extent not to exceed 400 units per quart. 2. The addition of vitamin A to food fats, to an extent not to exceed the amount of vitamin A in butter with high natural content of vitamin A. In both cases, when the added vitamin is obtained from a natural source no objection will be made if it carries with it one or more other vitamins. 3. The addition of iodine to table salt in an amount not to exceed one part sodium or potassium iodide per 5,000 parts salt. It is recognized that all three of these exceptions represent restorative additions of vitamins or minerals, as defined in resolution I.

The foregoing resolutions were adopted in principle by the Council on Foods, further details to be developed later. It also was decided that steps should be taken to acquaint the public and the medical profession with the Council's opinion that natural foods are to be preferred and that any foods restored with vitamins or minerals in accordance with the foregoing principles likewise are to be preferred over foods processed in a manner resulting in a loss of the dietary essentials which they might be expected to supply.

CLAIMS FOR FOOD PRODUCTS RICH IN CERTAIN VITAMINS

Discussion was made of the claims that could be recognized for wheat germ, yeast products and dried cereal grasses, all of which are considered as special purpose foods. The usefulness of these products is demonstrable by chemical analysis and biologic assay, together with a knowledge of the nutritional requirements for the various dietary essentials. Nutritional claims for these products should not exceed those recognized for the vitamins and other dietary essentials which they contain, due consideration being given to the amounts supplied by the portion, or dosage, which may be used daily.

VITAMIN MIXTURES

There have been developed by the industry numerous fabricated mixtures of vitamin preparations, which are marketed in the form of capsules. These contain usually preparations made from fish liver oils, supplying vitamins A and D, and extracts of yeast or other sources of vitamin B₁ and riboflavin. Sometimes vitamin C is included, although not many commercial preparations contain this factor. The field is not limited to capsules, but there is also a compressed yeast fortified with carotene and providing vitamin D and there are various tablets which likewise are sold to the public as vitamin preparations of relatively high potency.

These vitamin mixtures may be a commercial success, but they cannot replace the need for adequate amounts of a well balanced diet. Vitamin mixtures may have some reason behind the selection of vitamins which they contain and the amounts of each that are present, but if so, the reason is a "trade secret" which has not been divulged. Certainly there is no rational basis for placing in capsules amounts of vitamins A and D

which, in the amounts recommended by the firms, are several times a therapeutic dose, and amounts of vitamin B₁ and riboflavin which are almost insignificant compared to the contribution which an adequate diet would supply. Advertising campaigns and other efforts to promote the indiscriminate use of expensive polyvitamin mixtures are unfortunate because the "educational" program is not based on sound principles of nutrition or medicine. It is not denied that there may be a limited field in which polyvitamin mixtures might be useful, if the qualitative and quantitative composition of the mixtures were scientifically rational. It is conceivable, for example, that a physician might desire to provide a patient on a restricted therapeutic diet with vitamins which ordinarily are supplied by an adequate diet. But the available preparations of vitamin mixtures obviously cannot solve the problem of giving a patient the vitamins and food which he needs. The use of vitamin mixtures by the public is no assurance of "good health"; their daily use is no guaranty that all of the vitamins which a person must secure will be provided.

The Committee reaffirmed the policy of the Council on Pharmacy and Chemistry not to accept irrational fabricated mixtures of vitamins. The two councils concurred.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ANTIPNEUMOCOCCIC SERUM, TYPE I (See New and Nonofficial Remedies, 1939, p. 406).

Lederle Laboratories, Inc., Pearl River, N. Y.

Refined and Concentrated Antipneumococcic Serum, Type I—Lederle.—Also marketed in packages of one vial containing 20,000 units and one vial containing 50,000 units.

ANTIPNEUMOCOCCIC SERUM, TYPE II (See New and Nonofficial Remedies, 1939, p. 407).

Lederle Laboratories, Inc., Pearl River, N. Y.

Antipneumococcic Serum, Refined and Concentrated, Type II.—Also marketed in packages of one vial containing 20,000 units and one vial containing 50,000 units.

ANTIPNEUMOCOCCIC SERUM, TYPES I AND II COMBINED (See New and Nonofficial Remedies, 1939, p. 409).

Lederle Laboratories, Inc., Pearl River, N. Y.

Bivalent Antipneumococcic Serum, Refined and Concentrated.—Also marketed in packages of one vial containing 20,000 units and one vial containing 50,000 units.

ANTIPNEUMOCOCCUS SERUM, TYPES IV AND VIII COMBINED (See New and Nonofficial Remedies, 1939, p. 411).

Lederle Laboratories, Inc., Pearl River, N. Y.

Antipneumococcic Serum, Types IV and VIII, Refined and Concentrated.—Also marketed in packages of one vial containing 50,000 units.

ANTIPNEUMOCOCCUS SERUM, TYPES V AND VII COMBINED (See New and Nonofficial Remedies, 1939, p. 411).

Lederle Laboratories, Inc., Pearl River, N. Y.

Antipneumococcic Serum, Types V and VII, Refined and Concentrated.—Also marketed in packages of one vial containing 50,000 units.

TETANUS TOXOID, ALUM PRECIPITATED (See New and Nonofficial Remedies, 1939, p. 436).

Gilliland Laboratories, Inc., Marietta, Pa.

Tetanus Toxoid, Alum Precipitated (Refined)—Gilliland.—Marketed in packages of two 1 cc. and two 0.5 cc. vials each containing one immunization treatment and in packages of one 10 cc. vial and one 5 cc. vial each containing five immunization treatments.

CAFFEINE WITH SODIUM BENZOATE (See New and Nonofficial Remedies, 1939, p. 154).

Ampuls Caffeine with Sodium Benzoate, 2 cc.—Each 2 cc. contains in sterile aqueous solution caffeine with sodium benzoate U. S. P. 0.5 Gm. (7½ grains).

Prepared by the Wm. S. Merrell Company, Cincinnati.

SATURDAY, AUGUST 12, 1939

METABOLIC CHARACTERISTICS OF CANCEROUS TISSUE

The first significant advance in the study of the metabolism of tumors was made by Warburg,¹ who developed evidence of an altered carbohydrate metabolism of tumors. Thus was shown the ability of tumors to ferment aerobically from 90 to 95 per cent of available dextrose with the formation of lactic acid instead of oxidizing the carbohydrate to carbon dioxide and water as in normal tissue metabolism. This abnormal type of metabolism is not limited to malignant tissue, however. It has been found to be characteristic of all fast growing tissues. Kögl and Erxleben² have recently reported that several amino acids in malignant tissues occur as the unnatural stereo-isomers. While the significance of this remarkable fact cannot now be adequately evaluated, it is the first definite evidence of a qualitative difference in the metabolism of normal and malignant tissues.

An analysis of the protein hydrolysates of four malignant tumors indicated that as much as 42 per cent of the glutamic acid was present in the unnatural dextro-rotatory form. Lysine and leucine were also found as their unnatural stereo-isomers in smaller quantities. Similar hydrolysis of normal tissue yielded only the natural levorotatory forms of these amino acids. Since the enzyme system involved in the synthesis and degradation of each of the optically active isomers is highly specific, the presence of the unnatural forms would indicate that the particular tumor enzymes needed to metabolize these amino acids are less specific or are present in forms not native to normal tissue. The synthesis of protein, which is represented in the tumor by its rapid growth, is a result of the coordinating action of these different proteolytic enzymes; such a marked qualitative difference in behavior might greatly alter the rate of growth or regression (lysis) of the tumor.

In view of the important role which recent progress in biochemistry has given to glutamic acid in linking intermediary carbohydrate metabolism with protein metabolism, the results reported by Kögl and Erxleben are of special importance. Euler and his co-workers³ have separated from normal liver tissue a specific enzyme which, when supplemented with the oxidized form of coenzyme (dehydrocozymase), dehydrogenated glutamic acid, while, in the presence of the reduced form of the coenzyme, the enzyme synthesized glutamic acid from ammonia and α -ketoglutaric acid, which is a product of carbohydrate metabolism. Only the normal levorotatory form of glutamic acid is dehydrogenated by this enzyme from normal liver.

Braunstein and Kritzmann⁴ have further shown the importance of glutamic acid as a key substance in tissue metabolism by experiments in which the enzyme system of tissues was able to transfer the amino group from certain amino acids to α -ketoglutaric acid with the formation of glutamic acid, or reverse this transfer. While these authors found this transaminating enzyme system in all tissues except tumor tissue or nucleated red blood cells, Euler reports that it is present in tumor tissue but in smaller amounts than in muscle tissue.

The intensive investigations of tissue metabolism are constantly yielding new knowledge concerning the enzymic activities of normal and malignant tissues. If the observations of Kögl and Erxleben can be confirmed by other workers and it is found that all types of malignant tissues contain the unnatural forms of amino acids, a new and fertile field for study into the nature of cancer will be opened.

LISTERINE AND ALKA-SELTZER—THE FEDERAL TRADE COMMISSION TAKES ACTION

Some of the most interesting folklore in the development of American advertising—legends long accepted by many popular periodicals and by many people—is about to pass into the limbo of forgotten things. The Wheeler-Lea legislation seems to be functioning.

On August 3 the Federal Trade Commission entered into a stipulation with the Lambert Pharmacal Company of St. Louis, manufacturer of "Listerine Antiseptic," to cease and desist from "representing, by direct statement or by inference, that all dandruff is due to an infection with *Pityrosporon ovale* or any other organism; that dandruff necessarily is a germ disease; that the dandruff germ has been isolated or identified; that the presence of *Pityrosporon ovale* necessarily means dandruff or that with its destruction dandruff disappears; that dandruff is necessarily infectious, contagious or 'catching' or is in all instances passed from one person to another, or that any of the foregoing

1. Warburg, Otto: Ueber den Stoffwechsel der Tumoren, Berlin, Julius Springer, 1926.

2. Kögl, Fritz, and Erxleben, Hanni: Ztschr. f. physiol. Chem. 258: 57 (Nos. 2 and 3) 1939.

3. von Euler, Hans; Adler, Erich; Günther, Gunnar, and Das, Nalin Bandhu: Ztschr. f. physiol. Chem. 254: 61 (No. 2) 1938.

4. Braunstein, A. E., and Kritzmann, M. G.: Nature 140: 503, 1937. Enzymologia 2: 129, 1937.

assertions have been proven by findings of scientists or otherwise, or is a 'scientific fact' or a 'fact definitely established by scientists.'"

The Federal Trade Commission said, moreover, "that it is also stipulated that the respondent desist from representing that the product either cures or permanently relieves dandruff; that the product 'kills the dandruff germ,' 'attacks the cause of dandruff,' 'or gets at the cause' or 'at the root of the trouble' or penetrates infected hair follicles or 'annihilates' the dandruff germ; that the product frees the scalp and hair follicles of the parasite that saps their vitality or 'spreads a germ-killing film over the scalp'; that the product has 'marked curative properties due to certain ingredients in a unique combination shared by no other antiseptic'; that ordinary remedies 'aren't even antiseptic,' are 'smelly,' affect only surface symptoms, or merely remove surface symptoms temporarily, or that competitive products are obviously inferior to 'Listerine Antiseptic' as a remedy for dandruff—when such are not the facts."

The so-called research on which the claims of the manufacturer for this alleged virtue of listerine were based had never been accepted by competent dermatologists as authoritative; certainly there was not the slightest controlled evidence to indicate that listerine or any similar combination could have such virtue in controlling dandruff. Thus this product, which is essentially a formula like the liquor antisepticus of the National Formulary, will return to its original claims in relation to overcoming halitosis.

The history of the advertising of listerine as a preventive of halitosis has been told on many occasions. It laid the basis for many a vast advertising campaign associated with diseases discovered by advertising geniuses who thumbed the medical dictionaries. Out of the announcements of halitosis came such emphasis as has been placed on acidosis, athlete's foot, dyskinesia and similar conditions. The halitosis campaign reached its apotheosis with the advertisement which announced that "She Built Her Bridge Table Two Feet Wider." Obviously her breath could be detected two feet away but not four feet from her. Then she tried listerine and didn't have to stretch any more for the cards in the dummy.

The second decision of the Federal Trade Commission, dated August 6, involved a stipulation of the Miles Laboratories, Inc., Elkhart, Ind., with the Federal Trade Commission to discontinue misleading representation in the sale and distribution of Alka-Seltzer. This product is essentially a mixture of sodium acetylsalicylic acid with baking soda, and citric acid. Every one is familiar with the claims that have been made for the product over the radio and in other advertising.

Now the respondent company agrees "to cease the use of advertising matter implying that colds, neuralgia, distress after meals, and 'common everyday ailments' result from excess acidity of the blood, an acid condition of the blood, or deficient alkaline reserve of the blood,

and that alkalinizing effect of 'Alka-Seltzer,' by correcting such acid condition or restoring the alkaline reserve, will be a proper treatment for the ailments mentioned."

The respondent further agreed "to discontinue representations implying that headaches, upset stomach, and aches and pains result from, or are associated with, excess acidity of the blood, an acid condition of the blood, or a deficiency in the alkaline reserve of the blood, except when the ailments mentioned may be shown by competent scientific evidence to be directly associated with such conditions of the blood, and subject to this exception, to cease making representations implying that the taking of 'Alka-Seltzer,' by correcting the acid condition of the blood or restoring its alkaline reserve, will be a proper treatment for such ailments."

The respondent also stipulated "that it would cease representing that other therapeutic effects of 'Alka-Seltzer' exceed the recognized benefits to be derived from neutralization of hyperacidity of the gastric contents or the analgesic and other effects of sodium acetylsalicylate together with the action of buffer salts."

According to an examination of the product in 1932, persons who follow the directions to dissolve two tablets of alka-seltzer in a glass of water get nearly 9 grains of aspirin and nearly 1 grain of salicylic acid with their mixture of citric acid and baking soda. Those who do as suggested and take sixteen such tablets a day get over 70 grains of aspirin and 6 grains of salicylic acid in twenty-four hours. Whether or not the formula has been changed since that time is not known.

It will be interesting to see what the Miles Laboratories, Inc., find to talk about now that the government has told them what they cannot say. Perhaps they will decide to tell the people that what they are offering is essentially an effervescent tablet of aspirin.

THE NATIONAL HEALTH PROGRAM

The Seventy-Sixth Congress adjourned sine die August 5 without acting on the Wagner Health Bill, S. 1620. The Senate Committee on Education and Labor, however, submitted a preliminary report¹ August 4 and announced its intention to submit a definite report soon after the next session of Congress convenes. The subcommittee which has the bill under its immediate consideration plans to report an amended bill. The committee expresses the opinion that federal legislation along the general lines of the Wagner Health Bill is necessary to strengthen the health services of the nation and to make provision for progressive and effective improvement of health conditions in all parts of the country and among all groups of people. The committee was not convinced that the enactment of the bill would bring about revolutionary or dangerous changes in the established methods of medical service.

Congress passed in the last hours of the session just ended an act to amend the Social Security Act, and for other purposes, H. R. 6635, which covers primarily

1. Senate Report No. 1139, 76th Congress, 1st Session.

changes in the economic provisions of the act. In the Senate, certain amendments were added, later accepted by the House, largely increasing the amounts authorized to be appropriated for grants to states for maternal and child welfare, under the supervision and control of the Children's Bureau, and for public health work under the supervision and control of the Public Health Service. An amendment adopted by the Senate, proposing the establishment of an advisory council on disability insurance by the Committee on Finance of the Senate and the Committee on Ways and Means of the House of Representatives, in cooperation with the Social Security Board, was eliminated in conference.

On August 4, Senator Lodge of Massachusetts introduced a bill to provide health insurance to certain workers in severe economic distress, S. 2963. The bill proposes to provide certain limited medical and hospital services by physicians and hospitals chosen by the beneficiaries, but its benefits are to be limited to unemployed persons in need of medical and hospital services who during their periods of employment paid not less than certain stated amounts as taxes under the provisions of the Social Security Act. The bill was referred to the Senate Committee on Finance. Obviously it cannot be called up for consideration until Congress again convenes.

Current Comment

SCIENTIFIC AND COMMERCIAL CONSIDERATION OF VITAMINS

In this issue (page 589) appears a report by the Cooperative Committee on Vitamins of the Council on Pharmacy and Chemistry and the Council on Foods. The report, which is admirably succinct, is divided into two parts, one concerning vitamins as drugs and one dealing with vitamins as foods. The Council on Pharmacy and Chemistry again summarizes permissible claims for the use of vitamins in the prevention and treatment of disease. The report endorses the elimination by the American Society of Biological Chemists and the American Institute of Nutrition of the term "vitamin F"; this has not been established as a vitamin and has been commercialized by firms which have marketed cosmetics containing unsaturated fatty acids with the claim that these were "vitamin F." The Council recognizes the desirability of reducing the number of types of vitamin A and D preparations in different classes of manufactured products. There is certainly no necessity for the tremendous number of products, which vary from one another chiefly in the relative amounts of active ingredients, vitamins A and D, which they contain. The problems of the Council on Foods are complicated by the current tendency toward fortification of foods with excess of vitamins; some of this fortification is based on common sense but often there is no apparent basis except the desire to develop a product that can be sold. In general the Council on Foods feels that reconstruction of foods by the addition of vitamins lost in manufacturing processes is justified,

but mere fortification for the sake of fortification the Council cannot commend. The councils condemn heartily the needless, irrational and unscientific combinations of vitamins for treatment of diseases or for the alleged easy attainment of superabundant well being. This is the third report of the Council on Pharmacy and Chemistry in recent years on the status of vitamins; it indicates how rapidly research with vitamins and their clinical application move forward. Within the last few months vitamin B₆ has been synthesized, the chemistry of vitamin K has been clarified to a considerable extent, and evidence has accumulated about the significance of these factors and of riboflavin in human nutrition.

CORONARY OCCLUSION IN PHILADELPHIA

Hedley¹ has recently analyzed 5,116 deaths in the five year period ended Dec. 31, 1937, reported by the medical profession of Philadelphia as due to acute coronary occlusion. During this period the total mortality attributed to this cause increased more than 125 per cent in Philadelphia. In spite of the great increase in the number of deaths from coronary occlusion, however, the age distribution by decades and the mean age at death remain practically the same for all the years in the period under study. Hence it is concluded that the increase in deaths from acute coronary occlusion cannot be attributed to a tendency to report deaths among the very old as due to this cause. The ratio of males to females was approximately two to one. The mean age at death among all cases was 61.2 years. Further, the mean age at death and age distribution by age decades indicated that deaths among white females occurred at considerably older ages than among white males. Although acute coronary occlusion occurs less frequently among Negroes than among white persons, deaths from this cause among Negroes occur several years earlier. The mortality from this cause appears to be somewhat higher among the Jews than among white Gentiles. However, Hedley points out that this may be due to the large number of Russian Jews and may not prevail among native-born Jews. There was no definite seasonal variation of deaths from acute coronary occlusion as judged by the monthly distribution of deaths, although there were considerably fewer deaths during the warm months. The mortality rate among white persons increased from 36 per hundred thousand of population in 1933 to 84 in 1937. Among Negroes the increase was only from 25 to 27. The increase in reported mortality from acute coronary occlusion during this period cannot be attributed, Hedley says, to any great extent to the aging of the population in general or to the aging of the foreign born population in particular. Improvement in diagnosis was probably the main reason for the increase. In fact, the diagnosis of coronary occlusion cannot even yet be regarded as stabilized. Some further difficulties can be anticipated therefore in determining whether subsequent increases in the incidence of mortality from acute coronary occlusion are real or apparent.

1. Hedley, O. F.: Analysis of 5,116 Deaths Reported as Due to Acute Coronary Occlusion in Philadelphia, 1933-1937, Pub. Health Rep. 54: 972 (June 9) 1939.

ORGANIZATION SECTION

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

NEW MEXICO

In 1937 the New Mexico Medical Society Committee on Maternal and Child Health, which is composed of an obstetrician and a pediatrician and the secretary of the state society, advised the director of the Division of Maternal and Child Health of the New Mexico Department of Public Health regarding postgraduate instruction in obstetrics. At the request of the director, district health officers proposed postgraduate courses to members of various county medical societies throughout the state. In May 1938 physicians in two counties requested instruction, and an out of state obstetrician gave three lectures in each place. Twenty-two of the thirty-eight physicians in the two localities attended. No registration fees were charged, since federal funds were used. In September 1938 six other county medical societies were provided with instruction by another out of state obstetrician, who gave five two hour lectures in each county. Approximately seventy-nine of 141 physicians in these sections registered.

In May 1939 three county societies again requested the lecture courses in obstetrics, and one of the out of state obstetricians returned to New Mexico for the series. Movies were utilized and the instructor was available for consultations.

There are 419 licensed physicians in the state, of whom 256 are members of the New Mexico Medical Society.

TEXAS

ORGANIZATION AND ADMINISTRATION

The opinion has been expressed that in Texas postgraduate instruction may best be presented in medical centers of the state, their teaching facilities being utilized to advantage. Itinerant postgraduate courses would be difficult to organize to provide satisfactory programs in a state with sparsely settled areas and with varying geographic and climatic conditions. With these principles in mind, a postgraduate program in obstetrics and pediatrics for each of the fifteen councilor districts of the state was proposed in 1936 by members of the State Medical Association of Texas and of the Division of Maternal and Child Health of the Texas State Department of Health. The committee on maternal and child health of the state association, composed of ten practicing physicians, pediatricians and obstetricians with Dr. C. R. Hannah as chairman, and representatives of the state department of health provided the necessary machinery for the organization of postgraduate instruction.

INSTRUCTION IN OBSTETRICS AND PEDIATRICS

This committee in the succeeding two years sponsored the series of courses for physicians in thirty-nine communities and also provided a series of public health lectures. Instructors were chosen chiefly from the faculties of the two medical schools of the state and physicians in practice who were able to devote time to this effort. They arranged their own lectures to cover subjects outlined by the committee but worked under the direction of the state department of health. Honorariums and traveling expenses were paid instructors out of funds received by the department from the federal government.

The postgraduate medical instruction in obstetrics and pediatrics covered a period of not less than thirty hours given in three consecutive monthly programs of two days in each councilor district. Lectures, demonstrations and round table discussions were included. During the two years that the program of pediatrics and obstetrics was given, 1,291 practicing physicians received instruction. No registration fees were charged.

Each councilor district made its own provision for the conduct of courses in its respective locality. In each district a committee of three members with the councilor of the district as chairman had complete supervision of all postgraduate activities. County medical societies in turn appointed a local committee on arrangements, under the direction of the district committee.

The cooperation of the University of Texas School of Medicine, Galveston, and of the Baylor University College of Medicine, Dallas, the Texas State Dental Society, the Texas State Association of Obstetricians and Gynecologists and the Texas Pediatric Society was obtained in supporting this educational enterprise.

ACTIVITIES OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

In 1937 the committee on postgraduate instruction, with five members each appointed for one year, was formed by the state medical association. At that time the committee studied the postgraduate courses being given in Texas and the advisability of the state association adopting a similar program. The state association's ways and means committee had recommended that the association dues be raised \$1 a year in order to carry on scientific work successfully. It was also suggested that clinical conferences similar to those being given each year in Dallas, San Antonio and Houston be conducted by the state association each fall.

In 1938 the postgraduate committee emphasized the need for full cooperation of medical organization, medical schools and hospitals in promoting postgraduate instruction. It was believed that there was a need in Texas for additional opportunities for postgraduate training. The committee was of the opinion that this should take the form of extension medical courses made available through the facilities of the state medical association, the medical schools and the hospitals and should be carried to the home communities of as many physicians as possible. The two additional phases of postgraduate medical instruction which it was thought should be sponsored by the state medical association were (1) reestablishment of courses in fundamental medicine given during the summer several years ago in the medical schools and (2) formation of a speakers' bureau in the state association to give extension courses in its constituent societies. In 1939 the proposals made by previous committees of postgraduate medical education were considered but at that time no additional recommendations were made.

CLINICAL CONFERENCES

Three clinical conferences are given at different times each year in three cities of Texas. These are the Dallas Southern Clinical Society, Dallas, the Postgraduate Medical Assembly of South Texas, Houston, and the International Postgraduate Medical Assembly, San Antonio. On alternate years in El Paso postgraduate meetings of the Southwestern Medical Association are held. The clinical society of Dallas is an independent medical organization. The Houston society is sponsored by the three district societies of the state medical association and in San Antonio the postgraduate meeting is promoted by two district societies. Registration fees of \$10 each in Houston and in Dallas and income from commercial exhibits support the programs. This fee entitles the registrant to all the activities during the three or four day session. In San Antonio, dues from members and income from exhibits aid in financing. A centrally located hotel is used in each locality. Lectures, clinics, symposiums, round table discussions and, in one case, clinical pathologic conferences are given. Subjects of general

and special interest are included. Out of state instructors are provided, and in San Antonio both in state and out of state physicians participate. Attendance each year varies from 500 to 800 physicians. Operative clinics are sometimes held.

In addition to the annual clinical conference of the Dallas Southern Clinical Society, an extension service is available for scientific programs in county and district medical societies throughout the state. This is offered throughout the year in every field of medicine. Topics for discussion are selected by the local societies either singularly or in symposiums.

The Dallas Southern Clinical Society was organized in 1929 through the auspices of the Dallas County Medical Society and the membership of the clinical society includes 150 physicians of Dallas. Each member is required to take part in the extension service or to participate regularly in some educational program. The Postgraduate Medical Assembly of South Texas was organized in 1932. Local physicians do not participate in the programs of this society. The International Postgraduate Medical Assembly of Southwest Texas was organized in 1933. Full time executive secretaries and offices are maintained by two of these sectional societies.

In addition to the four metropolitan areas referred to, councilor district societies in other sections of the state hold one or two day postgraduate meetings. These include small clinics of the Tarrant County Medical Society held at Fort Worth each year, the district meeting held in Mineral Wells and the district meeting held in Amarillo. The Tarrant County Medical Society gave its first program of postgraduate instruction in 1906. At that time there were twelve courses offered by its members. From five to fifteen hour periods were devoted to such courses as anatomy, pathology, bacteriology, physiology, pharmacology, clinical diagnosis, medical jurisprudence and the history of medicine. At present this society conducts a one day clinic each year in which four or five out of state physicians participate. The program extends through twelve hours of the day. Meetings are held in a local hotel and lectures are illustrated with movies. The district meeting at Mineral Wells is similarly organized. Registration fees of \$1 are charged in each district and the attendance at each meeting varies from 200 to 300 physicians.

POSTGRADUATE ACTIVITIES IN MEDICAL SCHOOLS

Beginning in 1922 the University of Texas School of Medicine and the Baylor University College of Medicine cooperated with the committee on medical education and hospitals of the state medical association in organizing a postgraduate course of one week's duration each summer in the two institutions. These were review courses in general subjects of medicine. No registration fees were charged. The only expenses to physicians were cost of transportation and maintenance. Attendance averaged fifty annually in each institution. After two years, however, the courses were discontinued, since the faculties of the medical schools were not compensated for this type of instruction and had to forego periods usually devoted either to research or to vacation. This kind of instruction in teaching centers offered certain facilities that were not available to the same extent in other sections of the state.

OTHER POSTGRADUATE ACTIVITIES

The state medical association has offered a package medical library service to the physicians of Texas since November 1931. The library consists of a collection of more than 90,000 reprints and ten years open files of 160 periodicals in addition to more than 4,300 volumes available for mailing to members of the association. Unbound files of medical journals are kept for ten year periods. The library requires the services of one full time and one part time librarian. Twenty-five cents is charged each member requesting a library package.

INSTRUCTION OF NEGRO PHYSICIANS

Postgraduate instruction was first offered to the Negro physicians of Texas at Prairie View State College, Prairie View, in March 1937. This three day course of lectures and demonstrations was given under the joint sponsorship of the Texas Tuberculosis Association, the Texas State Department of Health, the Julius Rosenwald Fund and the Lone Star State Medical, Dental and Pharmaceutical Association. Subjects included were obstetrics, pediatrics, venereal diseases and

tuberculosis. Three out of state and seven Texas physicians gave the instruction. Fifty-seven practicing physicians registered for the course. In March 1938 the graduate assembly was repeated under the same auspices over a four day period. Four out of state and nine Texas physicians constituted the faculty. The use of clinical material was emphasized. A \$1 registration fee was paid by the fifty-nine who enrolled. In March 1939 a third four day assembly was held. Six out of state and seven Texas physicians gave the instruction, for which seventy-two practicing physicians registered. Clinical material was used in the demonstrations. Preventive medicine, communicable disease and antepartum and postpartum care were emphasized.

In addition to attending the annual postgraduate assemblies, Negro physicians of Texas have been offered the opportunity of obtaining two weeks of instruction at the Kerrville State Sanatorium. Six physicians registered. The Texas State Department of Health and the Texas Tuberculosis Association are sponsoring this intramural course also.

Of the 6,795 physicians practicing in the state, 4,483 are members of the State Medical Association of Texas.

VIRGINIA

ORGANIZATION AND ADMINISTRATION

In 1927 Dr. J. W. Preston, president-elect of the Medical Society of Virginia and chairman of the society's special committee on postgraduate study, enlisted the assistance and cooperation of the extension department of the University of Virginia to make a survey of postgraduate instruction in other states and to outline a suitable plan for continuation instruction for practicing physicians of the state of Virginia. As a result of this study Dr. J. Allison Hodges, chairman of the committee on medical education and hospitals of the state society, outlined such a plan in October 1929, which was adopted. The plan provided for the annual election of seven members of the society, who would compose the department of clinical and medical education as follows: three members chosen from the society membership at large (one the president-elect for the year, as chairman), one representative from each of the two medical schools in the state, one representative from the state health department and an executive secretary—either a physician or a layman.

The dominant idea in the formation of this department was that it provide a central medium between the society and its constituent units and act as a continuing and correlating body in providing postgraduate education to the practicing physicians of the state. It would assist local societies in securing suitable lecturers and clinicians and otherwise cooperate on request. An advisory board composed of members of the society's standing committees on medical education and hospitals and on scientific work in clinics aided the department.

From the beginning the department of clinical and medical education has provided practicing physicians in their own communities with lectures and clinics in recent advances in medicine, surgery, obstetrics and pediatrics. The department has aided in the establishment of a fully organized postgraduate clinical course in each of the medical schools of the state. It has assisted the state society in the publication and distribution of announcements of all courses and has published the names of physicians who have enrolled for postgraduate instruction. The director and the associate director of the extension division of the University of Virginia have acted as executive agents for the department and have donated their services and the facilities of the division to the medical society. The department has also had the cooperation of Dr. Warren F. Draper, state commissioner of health, who was able to obtain financial support for the program.

The state medical society has made a financial contribution yearly and practicing physicians have paid fees of from \$2.50 to \$10 for each course. After the plan was under way, the Commonwealth Fund of New York aided financially. With the assurance of added financial support it was possible to employ a competent physician full time to act as field clinician. The cooperation of the field organizer from the extension division of the University of Virginia made it possible to enlist the active support of county medical societies.

Instruction in obstetrics and pediatrics was desired and at first these courses were emphasized. Since 1937 instruction in medicine has been attempted. Instructors for the postgraduate courses until recently have been clinicians devoting full time to this work. At present faculty members from medical schools of the state give most of the instruction. They are compensated with small honorariums and travel expenses. Whenever possible, an effort is made to have registration fees sufficient to cover this expense. Service necessary for organization and administration is donated by the University of Virginia.

During 1930-1931, clinical meetings were held in eight counties of the state. Mr. George W. Eutsler, executive secretary for the department of clinical and medical education and associate director of the extension division of the University of Virginia, was responsible for sending notices to physicians in these areas. He also notified physicians of the postgraduate clinics being held in the medical schools of the state.

The chairman of the department of clinical and medical education, Dr. James C. Flippin, was active in supplying speakers for the meetings of county medical societies throughout the state. A speakers' list was printed in the *Virginia Medical Monthly* and reprinted in pamphlet form for distribution to the officers of county societies.

In January 1931 a grant of \$10,000 was obtained from the Commonwealth Fund and an appropriation of \$2,500 was made by the Medical Society of Virginia to continue the program of instruction in antepartum and postpartum care.

INSTRUCTION IN OBSTETRICS, GYNECOLOGY AND PEDIATRICS

From May 1932 to September 1933 Dr. Maxwell E. Lapham, field clinician, completed thirty-three classes covering the entire southern section of the state. Classes were grouped in six circuits, the first five having five centers each and the last having six. The registration at these short courses of two weeks' duration was 421. Two hundred and sixty-nine consultations were held and 184 patients were demonstrated in clinics.

Twenty-three classes were conducted during 1933-1934. Two hundred and twenty-nine physicians enrolled. There were 282 consultations with the field clinician, and 107 patients were demonstrated in the clinics. The tenth circuit, which included five towns, was completed in 1934-1935. Thirty-six physicians enrolled. Also during this year an out of state pediatrician directed a series of ten two hour lectures and demonstrations in two sections of the state. Twenty-eight attended one section and sixteen the other.

The general plan for this postgraduate instruction was to conduct lecture-clinics, having meetings of two hours' duration once a week for ten weeks in each locality. Every county medical society was given an opportunity to have the course. Usually the clinician lectured for one hour and then conducted a clinic or held an informal discussion during the second. On the day of the meetings he was available for professional conferences and bedside consultations. The first year the programs were held in the larger cities and towns of the state and the second year in the smaller towns and rural sections. Actually the percentage of physicians within reach of the clinics during the second year was higher than in the first.

During 1935-1936 the graduate program was less active partly because of insufficient financial support. Clinics were conducted by two out of state pediatricians in four sections of the state. With the aid of the state department of health, one full time instructor in obstetrics and one in pediatrics were employed to organize clinics and to continue the educational program of the state medical society, and the next year these field clinicians, together with members of the faculties of the two medical schools in Virginia, comprised the teaching staff for carrying on the postgraduate instruction.

There were ten circuits, which included thirty-three centers in which lecture-clinics were held in the subjects of obstetrics and gynecology. These courses reached physicians in forty-four counties of the state. The total attendance was 749. In addition, 178 consultations were held. Nine circuits in pediatrics included twenty-two centers accessible to physicians in twenty-nine counties. The total attendance was 972, and there were 476 consultations with physicians.

Postgraduate instruction in obstetrics and gynecology was completed during 1937-1938, it having been offered in every community of the state. Thirty-four counties were included that year with a total attendance of 957. One hundred and ninety consultations were held. The pediatric lecture-clinics were continued in thirty-four of the 100 counties in the state. The total attendance was 751, and 306 consultations were held.

OTHER TYPES OF INSTRUCTION

In cooperation with the department of clinical and medical education of the state medical society, two postgraduate clinics were held each year at the University of Virginia Hospital. These were given usually by members of the faculty of the department of medicine.

In 1936-1937 two postgraduate clinics were held by the department of medicine of the University of Virginia, forty-five practicing physicians attending one and 103 the other. Out of state physicians participated in this intramural instruction.

A short course in internal medicine was given in the eastern part of Virginia by local medical societies during 1937-1938. Twenty-eight physicians attended. The Medical College of Virginia provided instructors. Two other medical societies of the state conducted postgraduate instruction on a regional or county basis. The number of physicians attending the postgraduate clinics held by the University of Virginia Department of Medicine in 1937-1938 was 164.

A postgraduate course in internal medicine is now available to any county society of the state which requests this instruction. In 1938-1939, faculty members of the two medical schools have given courses with from three to six sessions in each of seven counties. These consist of lecture-clinics and round table discussions. In one county there was a total of ten weekly meetings. Registration fees vary from \$5 to \$10. Subjects for discussion are chosen by the physicians in each locality.

During 1938-1939 there was a symposium on the endocrines at the University of Virginia and a postgraduate clinic on general medical subjects. Eighty-one practicing physicians attended the first and fifty-nine the second session. A prominent out of state medical school instructor participated in each program. A symposium on vitamins was held in May 1939 in which three out of state physicians took part. Seventy-two practicing physicians registered for this day of graduate clinics.

Each year since 1930 the Medical College of Virginia has held an annual Stuart McGuire Lecture. From one to eight out of state physicians participate in this lectureship. In 1939 the lecture series was combined with postgraduate clinics and was devoted to a symposium on psychiatry. Lectures, discussions and demonstrations comprised the two day program. There was no registration fee. From thirty to fifty practicing physicians from Virginia attend these annual sessions.

The names of physicians who attend courses of instruction given by the state medical society appear in a special section of the *Virginia Medical Monthly*.

Courses continue to be financed by appropriations from the state medical society, registration fees and the state department of health. The total income, including registration fees and appropriation from the state society, is approximately \$1,500, which, together with the support from the state department of health and the organization and administration service donated by the extension division of the University of Virginia, has been sufficient to continue the program.

INSTRUCTION FOR NEGRO PHYSICIANS

The first postgraduate clinic for Negro physicians was held at the St. Philip Clinic, Medical College of Virginia, in June 1931. It was felt that there was need for better trained Negro physicians, and it was recognized that adequate postgraduate clinic facilities should be provided to keep them abreast of advances in medicine. The St. Philip Hospital for Negroes accommodates 131 patients in teaching wards and has laboratories available for special study. The General Education Board of New York City has given financial aid from the beginning. The Negro state and local medical associations cooperated in sponsoring this educational venture. Each year two weeks courses are offered to a group of from eighteen to forty-two colored physicians. A registration fee of \$10 is charged. Six hours is devoted each day to classes. There

are lectures, assignments of patients in the wards, demonstrations and bedside teaching. Instruction includes chiefly medicine as well as surgery, obstetrics and gynecology, clinical pathology, pediatrics and public health. Round table discussions are held on alternate days. Members of the first class met with members of the faculty and developed a plan providing for individual instruction. Each year one or more out of state physicians aid the medical college faculty in the instruction. In the fourth year clinical pathologic conferences featured the instruction and in the fifth year there were ten two hour periods devoted to surgical anatomy with actual dissection by members of the class. In that year seventy-nine members of the college faculty participated in the instruction.

Of those who registered for the St. Philip Hospital postgraduate clinics, approximately half practice outside of Richmond. Other than Virginia physicians, most of the applicants come from North Carolina, although such states as Alabama, Florida, Kentucky, Missouri, South Carolina, Tennessee and Texas have been represented.

Negro physicians who have attended these clinics petitioned the governor of the state to provide financial aid for their continuance. The state legislature however failed to provide sufficient funds, but the instruction continues each year at a cost of approximately \$1,250. This includes honorariums and expenses for publicizing the enterprise. Richmond physicians who have enrolled for this instruction in the past have requested the faculty of the Medical College of Virginia to aid them in giving additional postgraduate instruction during the year between the postgraduate clinics.

OTHER POSTGRADUATE ACTIVITIES

The Richmond Academy of Medicine gave a symposium on hematology, consisting of seven lectures which began in October 1938 and ended in February 1939. Six instructors from the medical schools of Virginia and an out of state medical school instructor comprised the faculty. Sixty-six practicing physicians attended this lecture series. A registration fee of \$3 was charged.

The library of the Medical College of Virginia offers a package medical service to any physician in the state who will pay the return postage on packages. From 120 to 150 out of town physicians use this service each year.

Of the 2,818 physicians licensed in the state of Virginia, 1,761 are members of the state medical society.

CORRECTION

DISTRICT OF COLUMBIA

In THE JOURNAL, July 15, page 237, there were said to be 2,141 physicians licensed to practice in the District of Columbia, of whom 872 are members of the Medical Society of the District of Columbia. The executive secretary of the society has since reported that there are 1,901 physicians licensed to practice in the District of Columbia, of which number it is estimated that from 1,000 to 1,100 are engaged in private practice, the remainder being employed by the district or federal government or have retired. The Medical Society of the District of Columbia at present has 885 active members, 169 associate members and seven honorary members, a total of 1,061.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Changes in Status.—The following bills have passed the Senate: S. 2745, authorizing the Commissioners of the District to promulgate and enforce all such reasonable rules and regulations as they may deem necessary to prevent and control the spread of communicable diseases in the District of Columbia; S. 2779, proposing to eliminate from the healing arts practice act in the District of Columbia the requirement that examinations be held on the second Monday in January and July of each year and to provide that such examinations may be held at such times as the Commission on Licensure to Practice the Healing Art may by rule or by special order determine; H. R. 4732 and H. R. 4733, proposing, respectively, to provide for the issuance of a license to practice chiropractic in the District of Columbia to George M. Corriveau and to Laura T. Corriveau; H. R. 6266, providing for the incorporation of certain persons as Group Hospitalization, Inc., the corporation to be authorized to enter into contracts with individuals or groups of individuals to provide for hospitalization of such individuals, to enter into contracts with hospitals for the care and treatment of such individuals, and to cooperate, consolidate or contract with groups or organizations interested in promoting and safeguarding the public health; and H. R. 7086, proposing to provide for insanity proceedings in the District of Columbia.

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 1540 has passed the House with amendments, proposing to increase the compensation of members of the National Advisory Health Council not in the regular employment of the government. A preliminary report on S. 1620 has been submitted to the Senate by the Senate Committee on Education and Labor. S. 1620 proposes to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of medical hospitals and health centers, care of the sick, disability insurance, and training of personnel. The Committee announced that a subcommittee appointed by it to consider the bill reported that it is in agreement with the

general purposes and objectives of the bill but wishes to give additional study to it and to consult further with representatives of lay organizations and of the professions concerned, in contemplation of reporting out an amended bill at the next session of Congress. S. 1899 has passed the House, providing for the detail of a commissioned medical officer of the Public Health Service to serve as assistant to the Surgeon General. S. 2284 has passed the Senate, authorizing the President to appoint 100 acting assistant surgeons for temporary service in the Navy. Senator Walsh, Massachusetts, explained that, whereas in the past mistakes had been made from time to time in giving permanent appointments to appointees who had not been tried out in the naval service, the purpose of the bill is to do away with permanent appointments until after appointees for temporary service have served a probationary period of eighteen months to determine their fitness and capability to perform the medical work required of surgeons in the Navy. It is contemplated that twenty-five of the 100 appointed will be eliminated so that the usual number of seventy-five permanent appointments will be made, as that number of surgeons yearly are required to take care of the health of the officers and enlisted men of the Navy. H. R. 6555 has passed the Senate, proposing to amend the law relating to the advance of funds in connection with the enforcement of acts relating to narcotic drugs, so as to permit such advances in connection with the enforcement of the Marihuana Tax Act of 1937. H. R. 6635, proposing to amend the Social Security Act, has been passed. As passed, the bill authorizes an increase in appropriations for maternal and child health services and services for crippled children, under the supervision and control of the Children's Bureau, and in appropriations for public health activities, under the supervision and control of the Public Health Service. An amendment, adopted by the Senate on the motion of Senator Wagner, to create an advisory council on disability insurance, to be established by the Committee on Finance of the Senate and the Committee on Ways and Means of the House of Representatives, in cooperation with the Social Security Board, was eliminated in conference.

Bill Introduced.—S. 2963, introduced by Senator Lodge, Massachusetts, proposes to amend the Social Security Act by adding a title XII, providing for a system of health insurance to

assist "qualified individuals to receive medical services when they require such care but are without means." A "qualified individual" is defined as one who has been registered as unemployed for at least fifteen consecutive weeks at a public employment office or other agency approved by the Social Security Board; is not receiving old-age benefits; before attaining the age of 65 has been paid, after Dec. 31, 1936, not less than \$5,000 in total wages from an employment as defined in section 210(b) of the Social Security Act; and has filed (1) an application for health insurance benefits, (2) a bill for medical or hospital services rendered to him and (3) the sworn affidavit of the attending medical practitioner or of the medical supervisor of the hospital that such medical or hospital treatment was furnished. It is proposed that every qualified individual shall be entitled in any year, on approval of his application by the Social Security Board, "to have forwarded to the doctor or hospital furnishing him with medical or hospital services, in part or full payment, for such services a sum equal to all or to any part of the health-insurance benefit to which such individual is entitled for such year," such benefit to be equal to one fifth of 1 per cent of such individual's total wages, except that such benefit shall not be in excess of \$25 for one year and the total of all such benefits shall not be in excess of \$100. The bill further proposes that any doctor participating in any false statement in connection with an application for benefits shall be reported by the Social Security Board to the state medical authority which issues and revokes licenses to practice medicine.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE, OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Personal.—Dr. Louis J. Saxe has been appointed superintendent of the Arizona State Hospital at Phoenix.—Dr. Frederick P. Perkins, Florence, who was for eleven years director of health at the University of Arizona, Tucson, has been appointed tuberculosis consultant to the state board of health.

Harlow Brooks Memorial Conference.—The fourth Harlow Brooks Memorial Navajo Clinical Conference will be held at the Sage Memorial Hospital, Ganado, August 28-30. The speakers will include:

- Dr. George W. Crile, Cleveland, The Antithetic Influence of Reason and Emotion in the Genesis of Coronary Disease and Hypertension.
- Dr. Ray M. Balyeat, Oklahoma City, Diagnosis and Treatment of Common Allergic Manifestations Encountered by the General Practitioner; Diagnostic and Therapeutic Value of the Use of Iodized Oil in Chronic Asthma and Bronchiectasis.
- Dr. Max Thorek, Chicago, The Surgical Obliteration of the Gallbladder Over the Gallbladder.
- Dr. Thomas G. Orr, Kansas, The Treatment of Fresh Wounds and Wound Healing; Management of Acute Intestinal Obstruction.
- Dr. Phil W. Shumaker, Los Angeles, Intra-gastric Photography.
- Dr. William H. Daniel, Los Angeles, Cancer of the Rectum.
- Dr. Frank R. Teachnor, Kansas City, Mo., Surgical Relief of Intractable Pain.
- Dr. William Warner Watkins, Phoenix, Correlation of Clinical and Roentgenological Evidence in Chest Disease.
- Dr. Charles A. Thomas, Tucson, Extrapleural Pneumothorax in Tuberculosis.

The registration fee for the conference is \$3, which covers all expenses. Rooms or dormitory space will be provided and meals will be served in the school dining room.

CALIFORNIA

Plague Infection.—According to *Public Health Reports*, June 23, plague infection has been proved in six ground squirrels, *Citellus beecheyi*, submitted to the laboratory of the state department of health April 25, from a point 1½ miles north of Rincon, Ventura County.

Courses for Practitioners.—Stanford University School of Medicine, cooperating with the San Francisco department of public health and the San Francisco Hospital, will offer a series of postgraduate medical courses for practicing physicians August 28-September 1. Morning courses will cover traumatic injuries and fractures, obstetrics, diseases of the genito-urinary tract and cardiology, while the afternoon courses will be given

over to diagnosis and treatment of malignant tumors, allergic diseases, neurology and psychiatry and surgical anatomy and operative technic. Ophthalmology and anesthesiology will be considered in the courses for specialists. The speakers at general meetings will be:

- Dr. Frederick L. Reichert, August 29, Peripheral Vascular Diseases.
- Dr. Garnett Cheney, August 30, Vitamin Therapy.
- Drs. Harry E. Alderson, San Francisco, and Merlin T.-R. Maynard, San Jose, August 31, Problems in Dermatology.

CONNECTICUT

New Society of Physical Therapy.—The Connecticut State Physical Therapy Society was recently organized with Drs. Harry E. Stewart, New Haven, president; Robert E. Peck, New Haven, and Charles Edlin, Waterbury, vice presidents, and Karl B. Bretzfelder, New Haven, secretary. The society was formally made a section of the Connecticut State Medical Society at its recent annual session.

DELAWARE

Society News.—Dr. Frederic H. Leavitt, assistant professor of neurology, Jefferson Medical College of Philadelphia, addressed the New Castle County Medical Society recently on "Trauma and the Central Nervous System."

Changes in State Board.—Dr. Arthur C. Jost, Dover, has resigned as executive secretary of the state board of health, effective August 10, according to the *Wilmington News*. Dr. Robert E. Ellegood, who has been a member of the board for twenty-three years, has also resigned, it was stated. Dr. Jost became executive secretary of the board Jan. 1, 1929, succeeding Dr. Arthur T. Davis, now at Riverhead, N. Y. He had formerly served as a county health officer in Nova Scotia and for ten years was in the provincial health department.

DISTRICT OF COLUMBIA

Mutual Health Service Begins.—The Mutual Health Service of the Medical Society of the District of Columbia was placed in operation July 1. Through this agency people of low incomes will be enabled to spread the cost of illness over a long period of time, according to *Medical Annals*.

Cornerstone Laid for Doctors' Hospital.—Ceremonies for laying the cornerstone of the new Doctors' Hospital were held in Washington July 11. Dr. Charles Stanley White is president of Doctors' Hospital, Inc. The principal speaker was Senator Robert A. Taft of Ohio. Among the guests were Drs. George C. Ruhland, District health officer; Lewis H. Taylor, president, Sibley Hospital; Thomas Parran, surgeon general, U. S. Public Health Service; William C. Woodward, former health officer of the District and now Director of the Bureau of Legal Medicine and Legislation, American Medical Association, Chicago, and Francis J. Eisenman, superintendent, Garfield Memorial Hospital. The \$1,500,000 Doctors' Hospital will be ten stories high and will offer accommodations for 250 patients. It will connect the two medical buildings, known as the Washington and Columbia Medical Buildings, which have as tenants about 250 physicians and representatives of the allied professions. Mr. Charles E. Vadakin, former manager of the Kahler Hospital, Rochester, Minn., will be superintendent.

FLORIDA

Personal.—Dr. Grady H. W. Brantley is the new mayor of Lake Worth, it is reported.—Dr. Leland J. Hanchett, passed assistant surgeon, U. S. Public Health Service, has been placed in charge of the division of venereal disease control of the state board of health, relieving Dr. Leo C. Gonzalez, Jacksonville, while he is taking a postgraduate course in venereal disease control and public health at Johns Hopkins University School of Hygiene and Public Health, Baltimore.

County Society Sponsors Newspaper Supplement.—A forty page medical section in tabloid form, sponsored by the Escambia County Medical Society, was published by the *Pensacola News-Journal* on Sunday, July 23. Among the features of the section were articles on the federal government and the medical profession, prepared by the executive committee of the Nassau County (N. Y.) Medical Society; an outline of the way in which the American Medical Association serves the profession and the American people, and numerous illustrated articles on various phases of medicine and public health. No by-lines of any members of the society were used. In a special announcement it was stated that the section was published under the sponsorship of the society; a committee passed on the news matter and advertisements. A list of the names of the society's officers and members followed.

ILLINOIS

Society News.—At a joint meeting of the Fulton and McDonough county medical societies in Bushnell June 20 Drs. James C. Redington and Frederic E. Hambrecht, Galesburg, spoke on "The Diagnosis of Pulmonary Tuberculosis" and "Surgical Treatment of Pulmonary Tuberculosis" respectively. —Dr. James J. Callahan, Chicago, discussed fractures before the Effingham County Medical Society in Effingham June 13.

Chicago

Resurvey of Venereal Diseases.—To determine the effectiveness of efforts toward the control of venereal diseases, a resurvey of all treatment sources is being planned in accordance with a request from Dr. Thomas Parran, surgeon general, U. S. Public Health Service, according to the Chicago Medical Society *Bulletin*. A campaign was begun throughout the state in June 1937 to bring patients with syphilis under medical care.

Retires as Professor of Oral Surgery.—Dr. Herbert A. Potts, for many years professor of oral surgery at Northwestern University medical and dental schools, will retire from the dental school at the end of the academic year September 1, with the title of professor emeritus. Dr. Potts, who also has the degree of doctor of dental surgery, has been associated with Northwestern University Dental School since 1908, first as lecturer in anesthesia, assistant in oral surgery, professor of pathology, instructor in oral surgery, assistant professor and since 1921 professor of oral surgery. He received his degree in dentistry at Northwestern in 1895 and his medical degree in 1901. He retired from the medical school as professor emeritus June 30, 1938.

Lay Cornerstone of Neuropsychiatric Institute.—The cornerstone of the Neuropsychiatric Institute, University of Illinois College of Medicine, was laid with appropriate ceremonies recently. Addresses were delivered, among others, by Arthur Cutts Willard, LL.D., president, University of Illinois; D. R. Kennicott, regional director, PWA; Dr. Richard H. Hutchings, Utica, N. Y., and Dr. Adolf Meyer, Baltimore. The cornerstone was laid by A. L. Bowen, director of the state department of public welfare, and the invocation given by Rev. Arthur E. Johnstone of the Episcopal City Missions. The building is expected to be ready for occupancy in the fall of 1940. More than \$500,000 of the approximate cost of \$1,300,000 has been supplied by PWA funds. The building, which will be eleven stories high, will be used for teaching neurology and psychiatry and for research in these fields (THE JOURNAL, Aug. 27, 1938, p. 851).

Annual Report of Tumor Institute.—A total of 505 patients representing twenty-two states, Canada, Cuba, South America and Spain were treated at the Chicago Tumor Institute during its first year of operation, according to its initial report recently released. Seventeen indigent patients were cared for without any referring physicians. There were 4,772 examinations made during the year; 1,299 x-ray diagnostic procedures and 1,975 treatments given with radium and 3,576 with x-ray. There were about twenty-five classifications of the types of cancer. Leading the list were: cancer of the breast, 104 cases; larynx, forty-three; cervix and uterus, twenty-six each, and tongue, twenty-three. The report acknowledges the arrangement with the veterans' hospital at Hines which has enabled the institute to utilize the clinical material at Hines to project special research on cancer of the larynx. The report emphasizes the need of an experimental laboratory to supplement the clinical investigations. Space is available but funds do not permit this activity. Another need of the institute is a library of current periodicals and monographs on cancer. During the year postgraduate instruction was given to about fifty specialists from all parts of the United States and from Hawaii, Cuba and South America. The teaching program of the institute is being developed on a comprehensive scale. The report classifies the program as follows: one year fellowships or traineeships; visiting fellows (from one to six months); postgraduate instruction to radiologists (from one to three months); short annual courses (one week) and weekly cancer clinics for fourth year students at Northwestern University Medical School (ninety students). The Chicago Tumor Institute, opened in March 1938, was chartered in Illinois, not for profit, to conduct research on the causes, diagnosis and treatment of cancer and to train cancer specialists. The institute has available 11 Gm. of radium, 10 Gm. of which is used in the form of a radium bomb. Dr. Max Cutler is director of the institute and Dr. Ludvig Hektoen is president of the board of trustees.

INDIANA

Personal.—Dr. Wesley M. Hoppenrath, Elwood, has been appointed regional medical examiner for the Civil Aeronautics Authority.—Dr. and Mrs. Joseph L. Reeve, Edwardsport, celebrated their golden wedding anniversary recently.

Hospital News.—A cancer institute will be established at the Protestant Deaconess Hospital, Evansville, next fall, it is reported. Dr. Keith T. Meyer, Evansville, will be in charge of the institute, which is said to be one of a series set up throughout the country under the auspices of the American College of Surgeons. Equipment valued at \$15,000 will be installed at the beginning and more will be added later.

IOWA

Personal.—The Dubuque County Medical Society held a special meeting in Sageville June 20 to observe the completion of fifty years in the practice of medicine by Dr. Bernard A. Michel, Dubuque. Drs. Martin E. Dittmer, Colesburg, who has practiced in Colesburg for fifty-two years, and John C. Dennison, who has practiced in Bellevue, for fifty years, were also guests of honor.

Society News.—Dr. Philip C. Jeans, Iowa City, discussed pediatrics before a joint meeting of the Bremer County Medical Society and the staff of Mercy Hospital at the Fortner Hotel, Waverly, June 28.—At a meeting of the Greene County Medical Society in Jefferson June 8 Dr. William F. Mengert, Iowa City, spoke on "The Management of Complicated Labor." —Dr. Lewis M. Overton, Des Moines, discussed common fractures before the Henry County Medical Society June 6.—Dr. Conan J. Peisen, Des Moines, addressed the Jasper County Medical Society in Newton June 13 on peptic ulcers.

LOUISIANA

Changes in Health Directors.—Dr. Lailor A. Morrogh, Jr., Arnaudville, has been appointed director of the Avoyelles Parish health unit, succeeding the late Dr. Lucius W. Holloman, Marksville.—Dr. Bert L. Stinson, Homer, has succeeded Dr. Walter W. Poimboeuf as head of the health service in Claiborne Parish.—Dr. Christopher L. Mengis, New Orleans, formerly director of the crippled children's division of the state board of health, has been appointed to succeed Dr. Stinson as director of the Iberia Parish health unit.

Dr. Barber Made President of State Society.—Dr. Dor-man B. Barber, Alexandria, has been made president of the Louisiana State Medical Society. He succeeds Dr. Clarence A. Lorio, Baton Rouge, who resigned following his indictment for embezzlement of Louisiana State University property. Dr. Barber graduated at Tulane University of Louisiana School of Medicine, New Orleans, in 1926. He is 39 years of age. Dr. Barber was first vice president of the medical society. Dr. Edwin L. J. Zander, New Orleans, was advanced from second to first vice president; Dr. Jean P. Mauboules Jr., Rayne, from third to second, and Dr. Walter O. Moss, Lake Charles, was appointed third vice president.

MICHIGAN

Society News.—Dr. Fred Z. Havens, Rochester, Minn., discussed plastic surgery before the Muskegon County Medical Society June 16.—Dr. Willard O. Thompson, Chicago, addressed the Berrien County Medical Society, Benton Harbor, July 13, on "Clinical Application of Male Sex Hormone in the Treatment of Disease."

Program of Postgraduate Education Expands.—The advisory council on postgraduate medicine of the Wayne County Medical Society, Detroit, has elected officers, including a registrar, secretary and executive secretary and formally launched "The Continuation School of Medicine of Wayne County," according to Detroit *Medical News*. The "school" proposes to offer courses in the specialties to general practitioners, using the facilities of the Wayne County Medical Society, the Detroit department of health, the hospitals, the department of welfare and the Wayne University College of Medicine. The courses will begin in the fall and will start with bedside teaching of general medicine for physicians in groups of from four to six. The days and hours chosen will be determined by mutual arrangement of the hospitals, the practitioners, and the teachers. Gradually, as the advisory council directs, other courses will be added on a basis of the highest teaching standards. It is probable that the next one will be on pathology.

Dr. William J. Stapleton Jr. is registrar of the "school"; Dr. David I. Sugar, secretary, and James A. Bechtel, LL.B., executive secretary. Executive management of the project will be governed by these officers, the executive officers of the county medical society and an advisory council.

Poliomyelitis Appears in Michigan.—Fifty-four active cases of poliomyelitis were reported from Detroit and eighteen from other parts of the state August 6. Since January 1 there have been ninety-two cases in the city, most of them since July 1. There have been six deaths in the recent cases. Scattered cases have been reported outside of Detroit, as follows: Saginaw, three cases; Oakland County, seven; Monroe, six; Calhoun, one, and Muskegon, one. Plans for combating the outbreak have been announced by local and state medical societies and health authorities. The committee on preventive medicine of the Michigan State Medical Society held a meeting in Detroit August 2 under the chairmanship of Dr. Ledru O. Geib, Detroit, at which arrangements were made for consultation service. Members of the American Academy of Pediatrics and the Michigan Orthopedic Society have agreed to render this service, which may be arranged through the office of the state medical society in Lansing. The state society has distributed about 2,000 copies of a brochure on poliomyelitis published by the American Medical Association to officers of county medical societies and physicians in the affected areas. The Detroit Department of Health has distributed literature to Detroit physicians and the Wayne County Medical Society has also been active. A conference was held July 31 with Dr. Edgar E. Martmer, chairman of the county society's committee on preventive medicine, as leader of the discussion. The National Foundation for Infantile Paralysis has allocated \$12,000 to finance an experimental laboratory to be established at Lansing under the direction of Dr. Sidney D. Kramer, Brooklyn, it was announced July 28. The Foundation will also provide funds for a respirator at Herman Kiefer Hospital, Detroit. Drs. James D. Trask, associate professor of pediatrics, and John R. Paul, associate professor of medicine, Yale University School of Medicine, New Haven, have been invited to lecture on poliomyelitis at a postgraduate conference at the hospital August 16. Dr. Alexander G. Gilliam of the U. S. Public Health Service is also in the state in connection with the outbreak. The public health service is reported to have made a grant of \$5,000 to aid in the establishment of the laboratory at Lansing. In addition to the Michigan outbreak, Sarnia, Ont., directly across the border from Port Huron, has reported nineteen cases with five deaths. The Ontario government has established a special laboratory in Sarnia to aid in handling the work.

MINNESOTA

Physicians Honored.—At a meeting of the council during the annual session of the Minnesota State Medical Association May 31-June 2 it was voted to present the distinguished service medal and scroll, awarded to members for special contribution to the work of the association, to the late Drs. William J. Mayo and Charles H. Mayo, Rochester, and Herman M. Johnson, Dawson. According to the state medical journal, photographs of the three will be hung at the University of Minnesota Medical School, Minneapolis. Dr. William Mayo died July 28.

MISSOURI

Personal.—Dr. John Aull, Kansas City, has been appointed a member of the state board of health.—Dr. Frank R. Bradley, St. Louis, has been appointed superintendent of Barnes Hospital, St. Louis, succeeding Dr. Louis H. Burlingham, who recently resigned, it is reported. Dr. Oswald N. Andersen, Chicago, a member of the staff of the Council on Medical Education and Hospitals, American Medical Association, has been appointed assistant superintendent.—Philip Anderson Shaffer, Ph.D., dean, Washington University School of Medicine, St. Louis, was awarded the honorary degree of doctor of science by the University of Rochester, Rochester, N. Y., at its recent annual commencement.

MONTANA

State Medical Election.—Dr. James I. Wernham, Billings, was chosen president-elect of the Medical Association of Montana at its annual session in Butte July 1 and Dr. Harold W. Gregg, Butte, was installed as president. Dr. Thomas F. Walker, Great Falls, was elected secretary, succeeding Dr. Thomas L. Hawkins, Helena, who had held the office since 1937.

NEW JERSEY

Law Authorizes Blood Tests for Paternity.—Authority to order blood tests in cases of disputed paternity is granted in a law passed by the state legislature and signed by Governor Moore July 18. The law requires that the tests be made by duly qualified physicians to be appointed by the court. This is the fourth law of its kind to be enacted by a state, the other states being Ohio, New York and Wisconsin.

NEW YORK

Annual Chautauqua Meeting.—The eighth annual interstate meeting of the Medical Society of the County of Chautauqua was held at Chautauqua Institution July 26. In the morning there was a scientific session with the following speakers: Drs. Arthur C. Christie, Washington, D. C., on "Diagnosis and Management of Cancer of the Breast"; George E. Hall, Toronto, Ont., "Reduction of Mortality Following Coronary Occlusion," and Russell L. Cecil, New York, "Sulfa-pyridine in the Treatment of Pneumonia." In the afternoon Dr. Christie and Dr. Cecil gave addresses at a public meeting.

Executive Secretary Dies.—Mr. Samuel A. Matthieu, executive secretary of the Medical Society of the County of Erie, Buffalo, died July 22 at his home, aged 67. Mr. Matthieu had been with the medical society for thirteen years. He was at one time associated with the New York Times.

New York City

Personal.—An item in THE JOURNAL July 22, page 342, announced that Dr. Philip R. Lehrman was recently promoted to be clinical professor of neurology and psychiatry at Columbia University College of Physicians and Surgeons. Dr. Lehrman writes that this should have been the New York Postgraduate Medical School and Hospital.—Dr. Israel S. Wechsler will present a paper at the Third International Neurological Congress in Copenhagen, August 21-25, on "Avitaminosis and Peripheral Neuropathies."

City Hospital Receives First Patients.—The city's new \$8,000,000 Hospital for Chronic Diseases on Welfare Island received its first patients July 6. Two hundred were transferred from City Hospital, also on the island. Within the next week 400 were to be moved from the old Neurological Hospital, 100 from Metropolitan Hospital, both on the island. In addition, 400 were to be brought from Kings County Hospital, Brooklyn. Twenty-four wards were to be occupied, leaving eight to be filled later. Dr. Chrisman G. Scherf is superintendent of the new hospital.

Physician Wins Refund on Telephone Rate.—A municipal court justice handed down a decision July 6 that a physician who maintains his office in his home is entitled to pay residence telephone rates, the New York Times reported July 7. The decision ordered the New York Telephone Company to pay Dr. Henry C. Eichacker \$131.56, representing the difference between the office rate and the residence rate from Jan. 7, 1931 to Oct. 1, 1936. The physician originally asked a refund from 1923, but the additional time was ruled out under the statute of limitations. The case had been previously heard by a different justice, who dismissed it. A new trial was granted after an appeal. It was said that if the ruling were upheld on appeal to a higher court, the telephone company would have to refund more than \$2,000,000 to physician subscribers in its territory.

NORTH CAROLINA

Changes in Health Officers.—Dr. Joseph A. Morris, Oxford, has retired as health officer of Granville County after twenty years of service. His successor is Dr. Ballard Norwood Jr., Oxford.—Dr. Wesley G. Byerly, Statesville, has been appointed health officer of the Burke-Caldwell district health department, succeeding Dr. Warren D. Carter, Morganton.—Dr. Clarence H. White, Newton, has resigned as health officer of Catawba County to study at Harvard University.

Society News.—Drs. Lowell H. Coleman, Spartanburg, S. C., and Lewis W. Hagna, Marion, among others, addressed the Thermal Belt Medical Society in Saluda July 20 on "Common Disorders of the Feet" and "Prognosis in Rheumatic Fever" respectively.—Dr. Claude G. Mentzer, Miami, Fla., was the guest speaker at a meeting of the Catawba Valley Medical Society, Lincolnton, July 14, on "Pathogenesis of Diseases of the Anal Region."—Dr. George M. Cooper of the state board of health, Raleigh, addressed the Johnston County Medical Society at Princeton June 27 on the board's work on infant and maternal care.—Drs. Charles J. Bloom, New Orleans, and Warren W. Quillian, Coral Gables, Fla., addressed the Buncombe County Medical Society, Asheville, July 31, on "Spastic Colitis in Infants and Children" and "Convulsions in Infants and Children" respectively.

MEDICAL NEWS

Society News.—Dr. John H. Moore, Grand Forks, was elected president of the North Dakota Society of Obstetrics and Gynecology at a meeting in Fargo recently; Dr. Albert M. Brandt, Bismarck, vice president, and Dr. August C. Orr, Bismarck, secretary.

OHIO

Professor Retires.—Dr. Elmer G. Horton, clinical professor and chairman of the department of pediatrics, Ohio State University College of Medicine, Columbus, has retired after thirty-seven years as a member of the faculty. Dr. Horton graduated in medicine at Ohio State in 1906 after having been professor of hygiene and physical culture at Wabash College, 1893-1895; instructor in hygiene, University of Pennsylvania, 1896-1898. He was also bacteriologist and chemist for the state board of health laboratories, 1898-1907, and health commissioner of Columbus, 1907-1909. He became assistant professor of pediatrics at Ohio State in 1914 and professor in 1924. He has been clinical professor since 1937.

PENNSYLVANIA

District Meetings.—The annual meeting of the Fourth Council District of the Medical Society of the State of Pennsylvania was held at Ashland June 29. The speakers were Drs. Edward L. Bortz, Philadelphia, chairman of the state society's commission on pneumonia control, on "Modern Treatment of Pneumonia, Including a Discussion of Sulfapyridine"; Belford C. Blaine, Pottsville, chairman of the commission on diabetes, "Diabetes—the Family Physician's Problem"; David W. Thomas, Lock Haven, president of the state society, "Medicine Faces Crisis," and Walter F. Donaldson, secretary, Pittsburgh, "The National Scene." The same speakers addressed a meeting of the Twelfth Council District at Dallas June 28 and in addition Dr. Rufus S. Reeves, Philadelphia, spoke on "The Role of the Clinician in the Health Department's Division of Cancer Control." Mrs. John H. Doane, Mansfield, president-elect of the Woman's Auxiliary to the state society, and Mrs. Donaldson, the present president, addressed meetings of the auxiliaries on both occasions.

Philadelphia

Blakiston Firm Changes Hands.—The publishing house of P. Blakiston's Son & Co., Inc., specializing in scientific and medical books, has been purchased from the estate of Kenneth M. Blakiston by Mr. Horace G. White, who has been executive vice president of the firm. The business was established in 1843 by Presley Blakiston and was continuously in the Blakiston family until the death of Kenneth M. Blakiston in 1937. It will now be carried on under the name The Blakiston Company. Mr. White will be president; Charles C. Norris Jr., and Robert F. Bowman, vice presidents; Edmund J. Glaser, treasurer, and Edward B. Barnes, secretary.

SOUTH CAROLINA

Dr. Guerry Honored.—Friends of Dr. LeGrand Guerry, Columbia, recently presented a bust of him to Columbia Hospital, where he has been surgeon since 1900. At the unveiling ceremony June 1 Reed Smith, Ph.D., professor of English at the University of South Carolina, made the principal address and two grandsons of Dr. Guerry unveiled the bust. Dr. Guerry graduated from the University of Georgia School of Medicine, Augusta, in 1896. He has been president of the South Carolina Medical Association, the Southern Surgical Association and the Tri-State Medical Association.

TENNESSEE

Society News.—Dr. Fred H. Albee, New York, addressed the Sullivan-Johnson Counties Medical Society at a meeting in Bristol, Va., June 7, on "The Surgical Use of Bacteriophage." —Drs. Robert Lyle Motley and William Milton Adams, Memphis, among others, addressed the Dyer, Lake and Crockett Counties Medical Society at a meeting at Reelfoot Lake June 7 on "Medical Treatment of Gallbladder Disease" and "Modern Concepts in the Treatment of Compound Facial Injuries" respectively. —At a meeting of the Five-County Medical Society (Hardin, Lawrence, Lewis, Perry and Wayne Counties) in Waynesboro June 27 the speakers were Drs. Charles Fowler Hollabaugh, Nashville, on "Management of the More Common External Diseases of the Eye"; Alva A. Jackson, Florence, Ala., "Conservative Treatment of Gallbladder Disease," and Murray B. Davis, Nashville, "Injuries of the Chest." —Dr. John S. Hawkins, Springfield, addressed the Robertson County Medical Society June 20 on toxemias of pregnancy.

NORTH DAKOTA

VIRGINIA

JOUR. A. M. A.
Aug. 12, 1937

Changes in Health Officers.—Dr. John C. Neale Jr. Staunton, has resigned as health officer of Augusta County and Dr. Vernon A. Turner, Richlands, formerly in charge of the Buchanan-Russell-Tazewell district, will succeed him. Dr. Neale will be in charge of the southwest district with headquarters at Abingdon. Dr. George R. Carpenter, formerly of Bristol, has been appointed health officer of Fairfax County to succeed Dr. Edward M. Holmes Jr., now on the staff of the state health department. Other appointments are: Dr. John B. H. Bonner, transferred from Prince George County to the Page-Shenandoah-Warren health district, Luray; Dr. Francis J. Clements, Stony Creek, from Sussex County to the Sussex-Prince George health district, Stony Creek; Dr. Chester L. Riley, Manassas, from Prince William County to the Sussex-William-Stafford health district, Manassas. Dr. Paul W. Bowden, Franklin, has been appointed health officer of Southampton County, succeeding the late Dr. Peter P. Causey, Courtland.

WEST VIRGINIA

Conferences on Obstetrics and Pediatrics.—A series of postgraduate conferences in obstetrics and pediatrics is in progress in ten towns forming two circuits under the auspices of the division of maternal and child hygiene of the West Virginia State Health Department and the maternal and child welfare committees of the West Virginia State Medical Association. In the southern section Dr. William J. Dieckmann, Chicago, is giving three lectures in obstetrics at weekly intervals and Dr. Edward L. Bauer, Philadelphia, two lectures in pediatrics. The towns in the southern circuit are: Bluefield, Williamson, Huntington, Beckley and Ronceverte. In the northern circuit Drs. Everett D. Plass and William F. Mengert, Iowa City, are lecturing on obstetrics and Dr. Lee Palmer, Louisville, Ky., on pediatrics in Weirton, Moundsville, Buckhannon, Elkins and Keyser. The series began July 17 and will end August 18.

WISCONSIN

Society News.—At a meeting of the Wood County Medical Society in Wisconsin Rapids, June 15, the speakers were Drs. Robert W. Mason, Marshfield, and Rogers E. Garrison, Wisconsin Rapids, on "Dislocation of Cervical Vertebrae"; Karl H. Doege, Marshfield, "Buerger's Disease with Myocardial Insufficiency"; Robert S. Baldwin, Marshfield, "Diabetic Gangrene," and Leo M. Morse, Neillsville, "Equine Encephalomyelitis." —Dr. Harold E. Marsh, Madison, addressed the Trempealeau-Jackson-Buffalo Tri-County Medical Society, Black River Falls, June 15, on "Cardiac Irregularities, Methods of Diagnosis and Treatment."

GENERAL

Society Urges Care for Handicapped Children.—The American Laryngological Association at its recent annual meeting adopted a resolution urging adequate programs for detection and correction of visual, hearing and speech handicaps in school children. The resolution points out that in many communities and rural districts little or no attention has been paid by school authorities to these disabilities affecting children. It then recommended "the provision of funds by foundations and other appropriate agencies to carry out adequate programs for the detection of visual, hearing and speech deficiencies which constitute a handicap to school children, and, for providing through the cooperation of qualified specialists and of state, county and local medical societies appropriate medical care for indigent and underprivileged children who may be afflicted or threatened with such handicaps."

Change in Date of Examination and Fees for Obstetric Board.—The next written examination and review of case histories (part I) for group B candidates of the American Board of Obstetrics and Gynecology will be held in various cities of the United States and Canada January 6, 1940, instead of December 2 as the board heretofore announced. Increases in the fees for the application and examination have been announced as \$15 and \$85 respectively. The board announces that it will hold only one group B, part I, examination this year prior to the final general examination, instead of two as in former years. Candidates who successfully complete the part I examination proceed automatically to the part II examination held in June 1940. Application for admission to group B, part I, examinations must be on file in the secretary's office not later than October 4. Dr. Paul Titus, 1015 Highland Building, Pittsburgh, is the secretary.

Society News.—The twenty-fourth National Recreation Congress will be held in Boston October 9-13. Additional information may be obtained from Mr. T. E. Rivers, secretary, National Recreation Association, 315 Fourth Avenue, New York City. —The Tri-State Medical Society (Arkansas, Louisiana and Texas) will hold its annual meeting at Marshall, Texas, November 8-9. Additional information may be obtained from Dr. Paul D. Abramson, chairman, program committee, 1130 Louisiana Avenue, Shreveport, La. Dr. Joseph D. Roberts Jr., Longview, Texas, is president. —The fifth International Congress for the Unity of Science will be held at Harvard University, Cambridge, Mass., September 3-9. Secretaries of the congress are Prof. Otto Neurath, International Institute for the Unity of Science, 267 Obrechtstraat, The Hague, Holland, and Charles W. Morris, professor of philosophy, University of Chicago.

Congress on Military Medicine.—Thirty-five governments were represented at the recent Tenth International Congress of Military Medicine and Pharmacy, held in Washington, D. C., May 7-15. The congress was followed by the ninth session of the International Office of Documentation of Military Medicine in New York May 15-19. Secretary of State Cordell Hull addressed the delegates in Washington. In addition to the scientific program, they visited Walter Reed Hospital, the Army Medical Museum, the Army Medical Library, the U. S. Naval Academy at Annapolis, the U. S. Military Academy at West Point and the medical field service school at Carlisle Barracks, Pa. Topics on the program included: organization and function of sanitary service in colonial expeditions; methods of determining the number of casualties; practical procedures for anesthesia and analgesia in war surgery; organization and functioning of the military chemico-pharmaceutical service; treatment of fractures of the maxillary bones; oxygen therapy and technical specialization for administrative officers in the medical services. It was proposed that an "institute of graduate medico-military studies" be created and opinions of each country are to be sent to the secretary-general of the International Committee of Military Medicine and Pharmacy, Colonel Voncken, Liège, Belgium, before April 1, 1940. The eleventh congress will be held in Switzerland in 1941.

Government Services

Cancer Institute Lends Radium

Hospitals in twenty states and the Territory of Hawaii will shortly receive loans of about 8.5 Gm. of radium from the National Cancer Institute, the U. S. Public Health Service has announced. The radium is now being tested by the U. S. Bureau of Standards and prepared for shipment in specially constructed lead containers. In approving applications, the officials of the institute made their choices on the basis of need for radium and the competence of staff and adequacy of facilities for radium treatment. The institute still has about 1,300 mg. of radium that has not been allotted and applications will continue to be received. Institutions receiving the loans must agree to make no charges to the patients for its use and must meet high standards regarding personnel administering the treatment.

Physicians Wanted for CCC Duty

Vacancies exist in the CCC in the Eighth Corps Area wherein the services of physicians can be utilized as civilian employees (physicians) or as contract physicians. Applicants should be graduates of class A medical schools and should address their applications to The Surgeon, Headquarters, Eighth Corps Area, Fort Sam Houston, Texas. Consideration will be given to applicants, as follows:

1. Medical reserve officers in the grade of captain or above who are eligible for active duty and promotion. They may be placed on duty under classification P-3 at the initial rate of pay of \$3,200 a year.
2. Medical reserve officers in the grade of first lieutenant, if qualified, may be placed on duty under classification P-2 at the initial rate of pay of \$2,600 a year.
3. Physicians who are not members of the medical reserve corps can be placed on duty as contract physicians at the initial rate of pay of \$2,600 a year.

All the candidates must consider themselves physically qualified and, if selected, must report to their first place of assignment at their own expense, and if found physically qualified they will be appointed at the respective rates. If on being relieved from duty, either at the request of the individual or for the convenience of the government, the return transportation must also be at the expense of the individual.

Injection of Pituitary Extract Immediately After Delivery

At the Section of Obstetrics and Gynecology of the Royal Society of Medicine, the effects of injecting pituitary extract immediately after delivery were discussed. Mr. S. G. Clayton tested the effects of injecting 5 units of solution of posterior pituitary immediately after delivery in eighty-three primigravidae and thirty-four multigravidae. He found that the duration of the third stage was slightly reduced—from an average of 16.7 minutes in primigravidae used as controls to fifteen minutes, and from 13.2 to 9.9 minutes in multigravidae. Then the amount of bleeding was investigated. In 117 test cases five showed a loss of more than 20 ounces (600 cc.), an incidence of 4.2 per cent, while in controls the figure was 3.8. Manual removal of the placenta was required five times in 372 control cases (three for hemorrhage, two for retained placenta); in 117 test cases it was required three times and in two retention was attributed to hour-glass spasm of the uterus. One primigravida was normally delivered after thirty hours' labor. Five units of solution of posterior pituitary was immediately given. After fifty minutes the placenta was still retained in spite of repeated attempts at expression and saline injection of the umbilical vessels. As slow loss continued, manual removal was attempted and a definite ring prevented passage of the hand until amyl nitrite was given and relaxed the ring. A second primigravida required similar treatment.

Mr. Clayton drew the following conclusions: 1. Solution of posterior pituitary slightly lessened the average duration of the third stage. 2. The incidence of postpartum hemorrhage was not reduced. 3. There is danger of hour-glass spasm of the uterus, with the ensuing risk of manual removal of the placenta. 4. It seems unjustifiable to expose the patient to this risk for the doubtful advantage of shortening the third stage.

In the second paper Mr. Clayton's conclusions were endorsed and in addition more than doubling of the incidence of postpartum hemorrhage was noted in the pituitary cases. But in the third paper this incidence was stated to be diminished and no tendency to a contraction ring was found.

Lord Horder Recommends Coeducation

In this country the rule, with very few exceptions, is to educate boys and girls in different schools, but Lord Horder, speaking on Parents Day at Bedale's School, Petersfield, Hants, one of the few schools where coeducation is practiced, recommended this system. His ideal school was one that would give the essential foundation of self discipline, good manners, cleanliness and punctuality. He would not bother so much about academic training. Nobody bothered about his. But he would bother about health, about food and more about rest to both body and mind. He would bother also about possibilities for manual work, some chance of close contact with the good earth. "I see in my consulting room the effects of coeducation as well as the effects of the lack of it. I think that coeducation is the natural thing, just as I think that the separate education of the sexes is the artificial thing. There must be, at least for the only child, great advantages in coeducation. For the children of families where the sex is the same the advantage of coeducation is also obvious. I have met in after-life those who had received the benefits of coeducation. I did not find that the boys were effeminate or the girls unfeminine."

Euthanasia Again Debated

Euthanasia, the right to die when suffering from painful incurable disease, is a subject of perpetual controversy. It is not legal for a physician to give a drug with lethal intent even at the request of the patient, and a bill to legalize euthanasia was recently defeated in the House of Lords. The subject has been debated from time to time at medical meetings but not at a public meeting such as has just taken place under the chairmanship of Mr. Neville Laski, a lawyer. The case for euthanasia was stated by Sir James Purves-Stewart, neurologist. He referred to a woman friend, suffering from a painful disease, who asked for something to make her sleep and never wake. "I will not say what action I took," he said, "but next day she failed to wake." "Some people charge us with murder," he continued. "I have received abusive letters to that effect, but murder is killing with malicious intent whereas voluntary euthanasia is an act of mercy. Individuals should be permitted to substitute a painless death for a slow and painful one. We do not propose that doctors would be allowed to kill all patients with incurable diseases." A Roman Catholic speaker said that the bill to legalize euthanasia was full of criminal possibilities. He doubted whether a man's will could be said to be sound when very ill and asked to sign a paper for euthanasia. It was usurping the prerogative of God. Sir Arnold Wilson, M.P., was not satisfied that in the words of Christ there was anything definite against euthanasia. Dr. Halliday Sutherland said that he knew of no instrument for judging pain like the thermometer which measured temperature. Pain was relative and in his experience Northern races of Europe suffered pain better than the Southern, and woman better than man.

When Purves-Stewart rose to reply there was an uproar in which cries of "Murder" were heard. He referred to the case of four men brought to a hospital scalded by a boiler explosion. When an attempt was made to take off their clothes the skin came away, exposing the muscles twitching all over the body. Their tongues and nostrils were so swollen that they could hardly breathe. "We gave each a huge injection of morphine and did not measure the quantity. Three died an hour later and the other in four hours. Was that a crime or an act of mercy?" A roar of conflicting answers came from the meeting. Summing up, Mr. Laski said that under the present law euthanasia was murder. "If this bill ever becomes law, I am not going to be one of the signatories."

The Shortage of Nurses and War Services

In the House of Commons a medical member, Sir Francis Edward Fremantle, called attention to the inadequate supply of nurses; 20,000 entrants to the profession were required yearly but only 12,000 were obtained. The long hours of work constituted the chief difficulty. Nurses of all grades suffered under a constant strain. Most hospitals were trying to reduce hours but were handicapped by a scarcity of recruits. The ninety-six hour fortnight was the utmost that could be achieved in the near future. Dr. Elliot, minister of health, said that the shortage arose from an increased demand; the number of nurses qualified annually had risen in ten years from 6,000 to 10,000. Many of the accusations about the conditions of service were exaggerated, but there was still scope for improvement.

WAR SERVICES

An important part of the subject was the aspect of war services. With regard to hospital bed expansion in time of war, in Great Britain 200,000 beds would be available in the first twenty-four hours. There would be beds in existing institutions for which a nursing staff was already provided. In addition, 100,000 beds were to be added to existing hos-

pitals for which the staff was not at present provided. Nurses and auxiliaries were also needed for first aid posts and for those millions of children and others to be evacuated from populous areas. The government was therefore asking for 100,000 volunteers. It wanted the big organized units of industry to give facilities to their staffs for training. He also appealed to retired trained nurses to register with the central emergency committees. There had already been substantial recruitment of Red Cross nurses, and some 7,000 untrained young women were undergoing training for qualification as nursing auxiliaries. But many more were required and he appealed to women to come forward.

Blood Donors In and Around London

This country has never been prepared for war in time of peace on any such scale as at present. The defense of the civil population against air raids is a new and immense problem. The blood transfusion service is a remarkable example of what is being done. At seventy centers throughout the country volunteers are being tested for their suitability as blood donors. All healthy men and women between the ages of 21 and 65 who are likely to be available at least during the early part of a war are asked to volunteer. Already more than 10,000 have been tested in the London area. For the center of London alone 100,000 volunteers are needed, and 250,000 for Greater London and the surrounding country. In the event of food becoming scarce, donors will be given extra rations to maintain the quality of their blood. After testing, donors are given a distinctive card stating to which of the four groups their blood belongs, so that in an emergency they will know where to report. Depots for the cold storage of blood, each equipped with at least 10,000 bottles and apparatus for its collection and distribution, have been arranged. The institution of these depots is based on experience in the Spanish war, in which Jorda's institute in Barcelona was a remarkable success. It was found that at least 10 per cent of the casualties could be saved by blood transfusion.

Henry Havelock Ellis

Henry Havelock Ellis, philosopher, critic and essayist, known the world over for his writings on sex and its aberrations, on which he was the first to write systematically in English, has died at the age of 80. An East Anglian, the son of a sea captain, much of his childhood was spent at sea. At 15 he went for his health in his father's ship to Australia, where he taught in various schools. In the solitude of the bush he passed through unhappy periods of storm and stress and decided that he would devote his life to elucidating the obscure problems of sex. For this purpose he returned to England and studied medicine at St. Thomas's Hospital. He qualified in 1889 at the age of 30. He practiced medicine for only a few months and gave himself up to literary work, in which he had been engaged even when a student. He edited the *Contemporary Scientific Series*, in which some important works appeared for the first time in this country. Among other books from his pen were *A Study of British Genius*, *The Philosophy of Conflict*, *The Criminal*, *The Task of Social Hygiene* and *The Problem of Race Degeneration*. His *Studies in the Psychology of Sex* appeared in 1898 but was not completed until 1910 and supplementary volumes appeared in 1928. In spite of protests from the medical press, it was suppressed by the government as obscene and he transferred its publication to an American publisher in Philadelphia. The work is now recognized as in the first scientific rank and to it is due most of the modern freedom of discussion of sex matters. He maintained that "we can never learn to reverence life until we know how to understand sex" and it is largely due to his teaching that sexual perversion is no longer regarded

as simply a matter of depravity but as a morbid phenomenon to be studied. An earlier book, *The New Spirit* (1890), emphasized the importance of sex in human affairs. *Man and Woman* (1894) was a study of human secondary characteristics and an introduction to a more elaborate investigation. Ellis was an idealist to whom money was a secondary consideration. It was only comparatively late in life that he received more than a bare living from the sale of his books. He was shy and retiring and never appeared in public or lectured.

PARIS

Tuberculosis Among Physicians and Nurses

The results of the tuberculin test in medical students and in student nurses have shown that the epidemiologic picture has been modified since the beginning of the century; 40 per cent of the recruits reporting for military training in France and 25 per cent of the students enrolling for medical studies have a negative cutaneous reaction. Rist has set forth before the Academy of Medicine statistics gathered by Heinbeck of Oslo and those of his own in the nurses' schools of the hospitals of Paris. Fifty-eight per cent of the members of one class numbering 144 and watched for two years showed a positive cutaneous reaction on entering. None of these had any trouble with their health while they were at school. Of sixty others, forty-four gave indication of change in the reaction; 10 per cent of these had a clinically proved tuberculosis, and one of them died. In the complete personnel of the Paris hospitals in which Rist has charge of matters pertaining to tuberculosis, 0.65 per cent (in 1931) were tuberculous, a figure reduced for 1938 to 0.37 per cent. Accordingly, the morbidity of the personnel constantly in contact with germ carriers is thirty times less than that of nurses in training. There is therefore an enormous difference between the risks of first year nurses with an allergic reaction and those with a negative cutaneous reaction.

How can one protect these young student nurses? Give them the allergic protection which they need by immunization with BCG vaccine. Heimbeck, who has employed this method, has ascertained that morbidity and mortality from tuberculosis were ten times less among nurses vaccinated and immunized than those not vaccinated. Since there still exists distrust against BCG inoculation, one must begin by recommending vaccination to nurses in training with a negative cutaneous reaction; compulsion may be considered subsequently. This vaccination should be parenteral by intradermal injections. It is strictly contraindicated in patients either allergic or in process of being rendered allergic.

Medicolegal Lecture on Blood Stains

At the last meeting of representatives of medical jurisprudence in Paris, Balthazard pointed out the conclusions which can be drawn in cases in which blood is projected on the ground, on walls or on other surfaces. He has confined his research to the laws by which stains left by blood are regulated. His technic consists in causing drops of blood to fall on different surfaces from varying heights and angles. These experimental studies are supplemented by cinematographic observations of the emission of the blood drops. Bull's electric spark process allows 500 photographs to be taken in a second during a period of time which cannot exceed one tenth of a second.

For drops falling on horizontal surfaces the problem is: Can one determine the height of the fall from the appearance of the drop? If the drop falls from a very low height, the stain

is circular. If it falls from a considerable height, points appear on the periphery. The number of these points depends on the height of the fall but still more on the volume of the drop of blood. The length of the points furnishes information of only a small degree of precision. Apart from the stains, more or less numerous jets can be observed; but neither their number nor their distance from the main body of the stain nor their volume yields indications of practical use. In criminal practice the most frequent type of blood stains are those which strike the surface on which they are observed obliquely. The stains lengthen out in proportion as the angle at which they strike is acute. The angle at which the drops fall is determined with great exactness by the relations between the length and breadth of the stain. Examination of the base of the stain reveals the height of the fall. Drops that fall from a height have a lengthened base like that of a brush. Stains are not homogeneous, especially if they are old. A crust formed at the lower end, becoming increasingly dark, may indicate the age of the stain.

The cinematographic examination of the fall of drops of blood has offered data on how to distinguish stains according to the origin of the blood; whether, for example, the blood comes from a wound or has been expectorated. In the same way, research has been made on how the appearance of a stain changes according to the object which the blood strikes (wall, paper, cloth). The problems are rendered complex by considerations such as adherence, lack of impregnation of the paints, fabric or paper, absence of expansion, variation in the spread according to the grain of the cloth, paper and felt, the contraction and desiccation of projected blood and the source of the projected blood (corpse or living person). The illustrations accompanying the paper of Balthazard and his collaborators may be exceedingly useful in medical jurisprudence.

Professional Guidance

France is a country of great individual liberty. Every one recognizes the importance of vocational orientation, but every one refuses to submit to constraint. Politics undertook to impose state control, but the reforms did not gain popularity. French parents will not admit that the state has all rights over their children. Neither did the French medical profession receive professional guidance sympathetically. One had no confidence in the technics of professional guidance, because of the enthusiastic assertions of their inventors. Hilaire, assistant general secretary of the confederation of French medical councils, presented the medical points of view before a recent meeting at the Institute of Professional Orientation. It is to the school physician who has received the necessary training that one must entrust the care of advising parents regarding the aptitudes of their children, what risk they incur in certain callings and the disappointments awaiting them in callings for which they are not adapted. The family physician can cooperate in this guidance by furnishing any information on the child which he has.

Institute of Cancer Research

An institute of cancer research was recently opened in North Lille. This is not a therapeutic center but has for its object the bringing together of all research activities. It is open to all research scientists, who will find in three kinds of laboratories (histophysiologic, chemical and physical) perfect equipment and a perfectly coordinated mechanization to aid them. The principle stressed is team work. This institute was created with subsidies received by Mr. Herbert Hoover and with the remainder of the funds of the American Committee for the Aid of Liberated Regions and of the Committee for Relief in Belgium.

BERLIN

News of the Universities

Secretary of education Rust has made a speech sketching the future inner construction of the universities. He never spoke more clearly. A problem of the universities found expression in the demand for shortening the period of academic study, as this previously has been done in case of medical students. The universities should now revise all their activities, including the plan of study. The laying aside of final examinations should be a temporary expedient. This the secretary admitted publicly. General exemption from school fees* in the higher grades (i. e. gymnasiums) is not yet practicable. Secretary Rust pointed furthermore to the necessity of closer ties between scientific preparation and practical training; in order to gain time the practical training should be done, partly at least, at the time of theoretical studies. The secretary believes that through variety created thereby also better results in studies could be obtained. Abbreviation of the duration of studies would place higher requirements also on the professors; they should observe the students in person to form an opinion of them. In such situation, said the secretary, the university professors should think less for once of their publications and more of the living body of men, as he expressed himself. The university professor should resolve now to be a teacher first of all (that is, not a researcher).

As the result of the lack of aftergrowth, with which all these efforts are concerned in the long run, one should act in three ways: (1) abbreviate the years of study, (2) prolong the duration of semesters and (3) connect more closely theoretical and practical training. The conference of rectors laid down finally twelve "points for the task of the German universities," which however contain nothing not generally known or not contained in the preceding parts. Two points read: "The fulfilment of the national tasks set for German science does not encroach on the freedom of instruction and research, which is an essential characteristic and solid foundation of the German university and of its idea of science." "The national socialist German university shall be the institution of higher learning of the German people." These two points are sufficiently characteristic. In this connection an utterance of the national student-leader, Dr. Scheel, is of interest. He has an influential position in university circles; he announced before 700 student sub-leaders that the national student council reserves its decision on the final form of the German university. Indeed, one has to consider that universities and intellectual life cannot be changed as rapidly as other fields. He gave clear warning, on the other hand, that the students could eventually look for their education at places other than the universities, for instance at the so-called castles of order, i. e. subleader training establishments of the national socialist party. The national student-leader actually said this. In the future admission will be possible only through selection undertaken by the party. Furthermore, Dr. Scheel was in favor of German students studying abroad. He added that the students one encounters today at some foreign universities as representatives of the German student body are unsuited to represent the national socialist deportment and conception of the world. Therefore the number of German students abroad should be greatly increased.

The regulation of formal admission of an academic lecturer into a faculty has already acquired a new form. The economic situation and the absence of aftergrowth of university professors as well as the new conditions created by the annexation of Austria and the Sudeten territory prompted the secretary to take these measures. The regulations concerning the obtain-

ing of a teaching post have undergone several important changes also as regards the economic security of the teachers. The obtaining of the teaching post is connected, besides the previous acquisition of the title "Dr. habil.," with successful participation at a course of the national camp for functionaries. In case the dean granted the admission to public trial-instruction, the candidate has to make three one hour lectures on three different days pertaining to his field of specialization; the subject of the lecture is chosen by the dean. This nearly corresponds to the procedure followed up to the present. In case of favorable decision, the secretary of education having the sole right to decide, with the appointment as a teacher (as up to the present), the candidate is admitted to the status of functionary at the same time; this is new and is valuable economically to the young teachers. The teacher who formerly had no claims for compensation for his teaching activity in Germany outside some income from lectures (mostly an insignificant amount) becomes a functionary. The secretary can appoint as extraordinary professors teachers who distinguished themselves in instruction and research; this appointment however does not establish any claim on the state and especially does not justify any expectancy of a full professorship. The authorization to teach, which is conferred exactly defined, that is limited to a definite branch of medicine, can be broadened with the consent of the secretary; it can also be restricted by the secretary in the interest of the university. An eventual changing of the university requires the consent of the secretary. According to this new regulation all teachers appointed heretofore and extraordinary professors not in office have to make a motion for appointment; should they fail to do this, they lose their teaching authorization as of Oct. 1, 1939.

The position of honorary professor was also defined in a recent decree of the secretary of education. Honorary professorship is not a title, it is an academic distinction. Scholars who do not belong to the teaching staff of a scientific institution of higher learning can be appointed honorary professors. They must be able to cooperate in the instruction and research problems of the faculty in conformity with their scientific accomplishments and meet the requirements of holders of academic professorial chairs. There is no admission to the status of functionary connected with the appointment by the secretary of education. The appointment does not create an employment relationship with the state and does not establish claims on the state, particularly for a university professorship. The appointment is valid as long as the appointee belongs to the teaching staff of the university. At the end of his sixty-fifth year the honorary professor needs the consent of the rector to continue his teaching activity. There are only a few honorary professors at the various faculties of medicine—mostly well known researchers in their fields. In the last years occasionally political considerations had their share in the appointment.

The question of academic aftergrowth is causing more and more concern. There often is a lack of appropriate persons to fill important professorial chairs. The gap created through the elimination of so many university professors by the well known proceedings of the last years cannot be filled by the present management of the German universities. A recent book gives a typical example of this exigency, as in case of university professors of law, of no special importance however. The author of this book, entitled "The German Professor of Law," is Professor Kisch, holder of a professorial chair at the Faculty of Law of the University of Berlin and in no way opposed to the present government. What he has to say therefore appears so much more significant. He speaks of "the very serious turn" of the problem of aftergrowth of university professors in the last years. There is a shortage of candidates and at times the quality of aftergrowth leaves much to be desired. It is quite difficult, in many cases impossible, to find suitable talent for vacancies of professorial chairs. The faculties of law supposedly

do not display any more the high quality they used to display. This situation is the result of the attitude of many influential groups with regard to university professorships. It is furthermore the result of the method of selecting the young aftergrowth, in which political considerations also take part. Hence the future university teachers have to attend a training camp for functionaries and "prove themselves" there, before they are appointed. In this connection the president of the national board of bar examinations also complained about the failures at the final examinations of legal studies and observed a "deplorable lack of knowledge" in the most important fields—a complaint already voiced by this office. This also is generally characteristic. Many of these claims are perhaps more easily understood in case one knows how higher government circles think about it. The secretary for propaganda, Dr. Goebbels, published an article recently under the title of "The Intellectual" in which he explained the notion of "intellectualism." To quote a few passages for the sake of illustration: "An intellectual is a man in whom civil valor is in inverse ratio to knowledge acquired through studies. . . . This intellectual is in reality an artificially highly bred accumulation of knowledge. . . . These men represent to quite an extent those who said 'no' to national socialism and to the work of the 'Führer' (leader) at every election. . . . There is no place in their black hearts for a great warm political passion." And the national student-leader, Dr. Scheel, recently said the following concerning the building up of student aftergrowth: "The aim is to produce a new type, separated by a world from a former flabby intellectualism." After taking note of these utterances coming from authoritative sources, one understands better perhaps some of the proceedings and complaints concerning the universities—and naturally this concerns the physicians.

BUENOS AIRES

July 15, 1939.

Hypertension and the Ischemic Kidney

Drs. Braun Menéndez and Fasciolo are carrying on some experiments started by Drs. Houssay, Fasciolo and Taquini. They experimented with the ischemic kidney in three conditions: (1) diminishing the lumen of the renal artery of a kidney which was transplanted to the neck of a dog, (2) also diminishing the lumen of the renal artery of a kidney which was irrigated with blood and (3) inducing total occlusion of the renal artery. It was verified in three cases that the kidney which has either an incomplete irrigation or is not irrigated at all produces a hypertensive and vasoconstrictor substance which passes into the blood. The truth of the statement is verified by three facts: (1) The transplantation of the kidneys in the neck of a normal dog induces a rapid increase of the arterial pressure of the animal, (2) the venous renal blood taken from the animal during the period of diminution of circulation and perfused through the surviving isolated circulatory system of a toad produces vasoconstriction and (3) if ischemia is done in such a manner as to permit the passage of 8 or 10 cc. of blood for each minute, and 100 cc. of the blood is collected during ten or fifteen minutes and given to a dog by intravenous injection during two or three minutes, the blood pressure of the dog increases. If the injection is done with venous blood of a kidney which is not in ischemia or else with carotid blood or with jugular venous blood, the blood pressure of the animal slightly increases. The results of the experiments prove that the ischemic kidney produces a hypertensive substance.

Diminution in Birth Rate

The birth rate in the population of Argentina shows a progressive diminution. It diminished from 39 in 1911 to 24 in 1937. The diminution is not due to economic factors, as it is observed

mainly in well-to-do families. Social and moral reasons are the main factors. Luxury and the demands of modern life are the causes for which conception is prevented. Several projects have been presented to the congress with the aim of establishing laws by which the birth rate may be stimulated and the families with children given economical remunerations.

Prevention of Goiter

Two bills have been presented before the house of senators for organizing a crusade against endemic goiter in Mendoza Province. In one of the bills there is an early allowance of 1,000,000 Argentine pesos (\$250,000) and 500,000 pesos (\$125,000) a year. In the other bill the figures for prevention of goiter and other work for sanitation of the province make an amount of 8,000,000 Argentine pesos (\$2,000,000).

Personals

Dr. A. H. Roffo was presented with the Amerongen prize, which was established for the production of cancer by feeding. Dr. Roffo had presented the results of the production of gastric cancer in rats. The animals had a diet of milk and bread, besides irradiated yolks of eggs, irradiated cholesterol and boiled lard and beef suet.

Dr. C. Fonso Gandolfo was appointed professor of infectious diseases at the Faculty of Medicine of Buenos Aires.

The Liga Francesa contra el cancer awarded the Amerongen prize to Dr. H. Roffo for his work on provocation of cancer from food in rats.

Profs. A. Sordelli and B. A. Houssay have been given the title of Officer of the Legion of Honor by the French government.

Deaths

Dr. Manuel Battaglia, secretary of the national department of hygiene of Buenos Aires, died February 23 of pulmonary edema.

Dr. Antonio A. Martinez, professor of pediatrics of the Faculty of Medicine of Buenos Aires, died January 19.

Marriages

WILLIAM CESYL BUSS, Bakersfield, Calif., to Miss Dorothy E. Hannon of Sunbury, Pa., at Pixley, Calif., recently.

WALKER THOMPSON, Iowa City, to Miss Mary Martha Gordon, formerly of Houston, Texas, March 11.

HAROLD PAGAN HOPE to Miss Helen Jeter Hamilton, both of Union, S. C., at Columbia, June 22.

ROBERT SPENCER HOWELL, Miami, Fla., to Miss Mary Louise Mullino of Montezuma, Ga., June 7.

LAWRENCE E. GEESLIN to DR. AMELIA BURNS SHEFTALL, both of Augusta, Ga., recently.

CHARLES W. IHLE JR., Cleghorn, Iowa, to Miss Helen Louise Hackett of Pittsburgh, July 1.

WILLIAM E. MOORE, New Haven, Conn., to DR. MARGARET I. HYDE of Baltimore, June 6.

GARTH EDMUND FORT, Nashville, Tenn., to Miss Chloë Frierson of Columbia in June.

CHARLES F. OWEN JR., Canton, N. C., to Miss Eloise Harniden of Philadelphia, July 10.

JAMES MYERS HICKS, Florence, S. C., to Miss Welker Delle Sellers of Mullins, June 15.

DAVID P. FINDLEY, Omaha, to Miss Lenore Hanson at Oconomowoc, Wis., April 22.

THEODORE SIDNEY RAIFORD to Miss Ann Irish, both of Decatur, Ill., June 20.

HENRY F. HALL JR., Columbia, S. C., to Miss Mary Hennies of Chester, July 4.

LEON HOSKINS, Harlan, Ky., to Miss Lida Lee Atkins of Pineville in June.

DAVID SCHREIBER to Miss Leah Cohen, both of New York, June 22.

Jour. A. M. A.
Aug. 12, 1937

Frederick Parker Gay * New York; Johns Hopkins University School of Medicine, Baltimore, 1901; an Associate Fellow of the American Medical Association; secretary of the Section on Pathology and Physiology, American Medical Association, 1914-1916; professor of bacteriology, Columbia University College of Physicians and Surgeons, New York, and formerly professor of bacteriology at the University of California Medical School, Berkeley; assistant and instructor in pathology at the Harvard Medical School, Boston, 1907-1910; member of the Association of American Physicians and the American Society for Experimental Pathology; served during the World War; member of the medical section of the National Research Council, 1917-1924, chairman in 1922 and chairman of the medical fellowship board, 1922-1926; was exchange professor at Belgian universities in 1926; author of "Studies in Immunity," 1909, "Typhoid Fever," 1918, and "Agents of Disease and Host Resistance," with others, 1935; contributed to scientific journals on bacteriology, immunology and pathology; aged 64; died, July 14, in New Hartford, Conn.

Stephen John Maher * New Haven, Conn.; Yale University School of Medicine, New Haven, 1887; past president of the Connecticut State Medical Society and the New England Conference on Tuberculosis; member of the Society of American Bacteriologists; for many years member of the board of the National Tuberculosis Association, and chairman of the State Tuberculosis Commission; was an official representative of the United States government at the International Tuberculosis Conference in Rome in 1928, Sweden in 1930, Lausanne in 1924, Amsterdam in 1932 and Lisbon in 1937; in 1932 received the Laetare Medal from Notre Dame University, South Bend, Ind.; for two years member of the city board of health; consulting physician to the Hospital of St. Raphael; member of the board of directors of the Gaylord Farm Sanatorium, Wallingford; aged 79; died, June 7.

Henri A. Lafleur, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1887; emeritus professor of medicine at his alma mater; member of the Association of American Physicians; was president and for many years member of the Medical Council of Canada; formerly vice president of the College of Physicians and Surgeons of the Province of Quebec; consulting physician to the Grace Dart Home Hospital and the Montreal General Hospital, where he died, June 4.

Ernest Cooper * State Park, S. C.; Johns Hopkins University School of Medicine, Baltimore, 1910; vice president of the South Carolina Tuberculosis Association; for many years superintendent of the South Carolina Sanatorium; formerly member of the board of directors of the National Tuberculosis Association; aged 62; died, May 6, at the Columbia (S. C.) Hospital of cardiovascular disease and bronchopneumonia.

Ova Portis Davis, Topeka, Kan.; University Medical College of Kansas City, Mo., 1896; Bellevue Hospital Medical College, New York, 1897; member and past president of the Kansas Medical Society; past president of the Shawnee County Medical Society; formerly professor of principles and practice of medicine at the Kansas Medical College; on the associate staff of the Christ's Hospital; aged 69; died, May 28.

Robert Drane Jewett, Wilmington, N. C.; University of Virginia Department of Medicine, Charlottesville, 1888; member, and secretary 1893-1898, of the Medical Society of the State of North Carolina; owned and edited the *North Carolina Medical Journal*, 1892-1898; aged 79; died, May 6, in the James Walker Memorial Hospital of lobar pneumonia.

Gilbert Royce, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1897; formerly professor of otolaryngology at his alma mater; fellow of the American College of Surgeons; served during the World War; on the staffs of the Victoria Hospital for Sick Children and the Toronto General Hospital; aged 69; died, May 23.

Archer Dorval Babcock, Syracuse, N. Y.; University of Buffalo School of Medicine, 1893; member of the Medical Society of the State of New York; served during the World War; on the staff of the Crouse-Irving Hospital; aged 69; died, May 25, of cerebral thrombosis, chronic endocarditis and coronary infarction.

Albert Fay Lowell * Gardner, Mass.; University of Vermont College of Medicine, Burlington, 1900; fellow of the American College of Surgeons; attending surgeon to the Henry

Heywood Memorial Hospital, Gardner (Mass.) State Hospital and the Peterboro (N. H.) Hospital; aged 63; died, May 14, of pneumonia.

Samuel Harris Newman, Dadeville, Ala.; Memphis (Tenn.) Hospital Medical College, 1898; member of the Medical Association of the State of Alabama; past president of the Tallapoosa County Medical Society; at various times member of the local school board and city council; aged 71; died, May 19, of myocarditis.

Chester Harris Sample, Saginaw, Mich.; Bellevue Hospital Medical College, New York, 1874; member of the Michigan State Medical Society; fellow of the American College of Surgeons; past president of the Saginaw County Medical Society; surgeon to St. Mary's Hospital; aged 88; died, May 3, of senility.

Rollin Roy Nevitt * Moran, Kan.; Kansas City (Mo.) Homeopathic Medical College, 1896; past president of the Allen County Medical Society; served during the World War; aged 69; died, May 14, in the Mercy Hospital, Fort Scott, following a cholecystostomy, cholelithiasis and postoperative pneumonia.

Arthur Edward Williams, Rock Island, Ill.; Northwestern University Medical School, Chicago, 1902; member of the Illinois State Medical Society; past president of the Rock Island County Medical Society; aged 63; on the staff of St. Anthony's Hospital, where he died, May 25, of heart disease.

Claude Carl Lytle * Geneva, N. Y.; Syracuse University College of Medicine, 1900; fellow of the American College of Surgeons; for several years member of the board of health; attending surgeon to the Geneva General Hospital; aged 65; died, May 3, of diabetes mellitus and coronary embolism.

James Lewis Pierce, Marianna, Fla.; Emory University School of Medicine, Atlanta, 1926; member of the Florida Medical Association; formerly secretary of the Jackson County Medical Society; aged 38; was killed, May 27, in an automobile accident near Thomaston, Ga., en route to Atlanta.

David McClurg, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; member of the Michigan State Medical Society; on the staff of the Highland Park (Mich.) General Hospital; aged 74; died, May 25, of hypertension and coronary occlusion.

Edward Francis Day * Binghamton, N. Y.; University of the City of New York Medical Department, 1895; on the staffs of the Binghamton City Hospital and Our Lady of Lourdes Memorial Hospital; aged 67; died, May 18, of chronic arthritis, aplastic anemia and ulcerative colitis.

James F. Rosborough, Marshall, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1893; member of the State Medical Association of Texas; past president of the Harrison County Medical Society; aged 83; died, May 13, of coronary thrombosis.

Millard Percy Doyle, Norfolk, Va.; Medical College of Virginia, Richmond, 1907; member of the Medical Society of Virginia; on the staffs of the Norfolk General Hospital, Leigh Memorial Hospital and St. Vincent's Hospital; aged 58; died, May 8, of coronary occlusion.

Henry Chilton Osborn, Ashland, Ky.; University of Louisville Medical Department, 1910; member of the Kentucky State Medical Association; served during the World War; on the staff of a cerebral hemorrhage.

James A. Reeder, Clare, Mich.; Detroit College of Medicine, 1898; member of the Michigan State Medical Society; officer; aged 76; died, May 7, in the Harper Hospital, Detroit, of Hodgkin's disease.

Coalby T. Rives, Winters, Texas; College of Physicians and Surgeons, Little Rock, Ark., 1911; member of the State Medical Association of Texas; past president and secretary of the Runnels County Medical Society; aged 65; died, May 14, of chronic nephritis.

Joseph Aloysius Dillon * New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894; served on the staff of the New York Foundling Hospital in various capacities; aged 69; died, May 3, of angina pectoris.

Harold Fredrich Neilsen, Minneapolis; University of Minnesota Medical School, Minneapolis, 1930; member of the Minnesota State Medical Association; formerly deputy coroner; aged 34; died, May 23, in the Swedish Hospital of pulmonary tuberculosis.

Joshua Milburn Dougherty Jr. * Gate City, Va.; Medical College of Virginia, Richmond, 1925; secretary of the Scott County Medical Society; on the staff of the Holston Valley Community Hospital, Kingsport, Tenn.; aged 38; died suddenly, May 4.

DEATHS

613

- Alfred Raymond Lozano**, Montgomery, Ala.; Université de Paris Faculté de médecine, France, 1932; member of the Medical Association of the State of Alabama; aged 34; died, May 18, in Corpus Christi, Texas, of carcinoma of the tongue.
- Henry G. B. Nixon** Ⓢ Hartland, Wis.; Detroit College of Medicine, 1887; bank president; formerly on the staffs of the Municipal Hospital, Waukesha, and the Summit Hospital, Oconomowoc; aged 73; died, May 19, of coronary thrombosis.
- Francis Albert Hargrave**, Palo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; member of the Michigan State Medical Society; for many years member of the school board; aged 82; died, May 6.
- Jay O. Spinning**, Litchfield, Mich.; Hahnemann Medical College and Hospital, Chicago, 1876; aged 86; died, May 28, in the James W. Sheldon Memorial Hospital, Albion, of pulmonary infarction following a cystotomy, and prostatism.
- Charles Fernando Myre**, Chippewa Falls, Wis.; School of Medicine and Surgery of Montreal, Que., Canada, 1899; aged 66; on the staff of the Northern Wisconsin Colony and Training School, where he died, May 5, of chronic myocarditis.
- William John Scott**, Cookstown, Ont., Canada; University of Toronto Faculty of Medicine, 1918; served during the World War; aged 44; died, May 7, of injuries received when he fell from the fifth floor balcony of a hospital in Toronto.
- Charles Spurgeon Strain**, Rochester, Mich.; Detroit Homeopathic College, 1902; member of the Michigan State Medical Society; served during the World War; aged 68; died, May 16, in a hospital at Pontiac of heart disease.
- William R. Hand**, Fargo, N. D.; Cincinnati College of Medicine and Surgery, 1877; member of the Minnesota State Medical Association; aged 82; died in May of obstruction of the common duct, gallstones and myocarditis.
- Albert Herrick Thornton**, Edgemont, S. D.; State University of Iowa College of Medicine, Iowa City, 1898; medical director of the Edgemont Hospital; aged 64; died, May 22, of chronic myocarditis following a chordotomy.
- William Claude O'Neal**, Palmyra, Mo.; St. Louis University School of Medicine, 1904; member of the Missouri State Medical Association; aged 64; died, May 20, in the St. Elizabeth's Hospital, Hannibal, of myocarditis.
- Albert K. Barrier**, Rolling Fork, Miss.; Kentucky School of Medicine, Louisville, 1885; member of the Mississippi State Medical Association; formerly county health officer; aged 80; died, May 31, of Parkinson's disease.
- Eli G. Alcorn**, Columbus, Ohio; University of Louisville (Ky.) Medical Department, 1895; formerly coroner of Gallia County; at one time member of the board of education of Gallipolis; aged 94; died, May 1.
- Benjamin Smith Parks**, Parkersburg, W. Va.; Barnes Medical College, St. Louis, 1906; member of the West Virginia State Medical Association; aged 56; was found dead in his garage, May 19, of asphyxiation.
- William George Zantiny** Ⓢ Long Beach, Calif.; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1908; on the staff of the Community Hospital; aged 61; died, April 12.
- Webb Suter**, Campbellsburg, Ky.; Hospital College of Medicine, Louisville, 1905; member of the Kentucky State Medical Association; aged 59; died, May 23, in the Kentucky Baptist Hospital, Louisville.
- Francis S. Wildner**, Poughkeepsie, N. Y.; Deutsche Universität Medizinische Fakultät, Prague, Hungary, 1906; member of the Medical Society of the State of New York; aged 58; hanged himself, April 30.
- Wilfred Teller La Fortune**, Fitchburg, Mass.; Baltimore Medical College, 1910; member of the Massachusetts Medical Society; served during the World War; aged 52; died, May 8, of coronary thrombosis.
- Hugh John Duffy**, Chicago; University of Illinois College of Medicine, Chicago, 1911; served during the World War; aged 50; on the staff of St. Francis Hospital, Evanston, Ill., where he died, May 8.
- John Andrew Tomasi**, Bennington, Vt.; Georgetown University School of Medicine, Washington, D. C., 1934; aged 32; died, April 27, in the Caverly Preventorium, Pittsford, of pulmonary tuberculosis.
- Horace Luten**, Fulton, Ky.; University of Louisville Medical Department, 1898; served during the World War; aged 65; died, May 11, in the Illinois Central Hospital, Paducah, of coronary occlusion.
- William Robert Hazlewood** Ⓢ Austin, Texas; Louisville (Ky.) Medical College, 1898; superintendent of the Austin State School; aged 68; died, May 15, of carcinoma of the esophagus and mediastinum.
- Oliver J. Paris**, Graham, N. C.; Baltimore Medical College, 1897; aged 72; died, May 2, in the Piedmont Memorial Hospital, Greensboro, of strangulated hernia, chronic nephritis and myocarditis.
- Harrie Abijah James**, New York; University of the City of New York Medical Department, 1891; member of the Medical Society of the State of New York; aged 78; died, May 2, of heart disease.
- Christopher Columbus Gleaves**, Los Angeles; Northwestern Medical College, St. Joseph, Mo., 1889; University of California Medical Department, San Francisco, 1889; aged 77; died, April 12.
- Terry Kinney**, San Marcos, Texas; University of the South Medical Department, Seawane, Tenn., 1895; member of the State Medical Association of Texas; aged 71; died, May 3, of heart disease.
- Robert Ellsworth Van Wickle**, St. Louis; University of Pennsylvania School of Medicine, Philadelphia, 1937; an intern at the St. Louis Maternity Hospital; aged 31; died, May 14, of heart disease.
- Robert T. Prine** Ⓢ Ripley, Ohio; Medical College of Ohio, Cincinnati, 1897; past president of the Brown County Medical Society; aged 63; died, May 27, of arteriosclerosis and chronic myocarditis.
- Alfred W. Gross**, Chattanooga, Tenn.; Chattanooga Medical College, 1903; member of the Tennessee State Medical Association; aged 58; died, May 22, in the Newell and Newell Sanitarium.
- Charles Jerome Bright Cave**, Garrison, Barbados, B. W. I.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1907; medical missionary; aged 59; died, May 19.
- Jackson Brainard Pellet**, Hamburg, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1871; aged 91; died, May 3, of heart disease.
- Roche W. Hogeboom** Ⓢ Springfield, Mo.; Rush Medical College, Chicago, 1897; fellow of the American College of Surgeons; on the staff of St. John's Hospital; aged 63; died, May 1.
- Edson Carey Miller**, Brookings, S. D.; Chicago Medical College, 1874; member of the South Dakota State Medical Association; aged 92; died, May 21, of cerebral hemorrhage.
- Joseph F. Miller** Ⓢ Palmer, Ill.; Missouri Medical College, St. Louis, 1889; for many years bank president; aged 82; died, May 6, in St. Vincent Hospital, Taylorville, of pneumonia.
- Edward Bancroft Rogers** Ⓢ Collingswood, N. J.; College of Physicians and Surgeons, Baltimore, 1903; aged 61; died, May 12, in the Cooper Hospital, Camden, of pneumonia.
- Ernest Maynard Freeman**, Redlands, Calif.; University of California Medical Department, San Francisco, 1893; aged 74; died, April 27, of coronary occlusion and hypertension.
- Margaret Josephine O'Sullivan** Ⓢ Omaha; University of Nebraska College of Medicine, Omaha, 1927; aged 57; died, May 2, in the Immanuel Hospital of carcinomatosis.
- Tonnes O. Ries** Ⓢ Luck, Wis.; Milwaukee Medical College, 1911; aged 59; died, May 28, in St. Croix Falls (Wis.) Hospital of injuries received in an automobile accident.
- Carl J. F. Rochow** Ⓢ Rock Island, Ill.; Rush Medical College, Chicago, 1903; aged 61; on the staff of St. Anthony's Hospital, where he died, May 11, of heart disease.
- John Isaac Pratt**, Port Arthur, Ont., Canada; University of Toronto Faculty of Medicine, 1895; L.R.C.P., London, M.R.C.S., England, 1902; aged 65; died, May 3.
- Otto Clarke Dunsworth**, Trenton, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1907; aged 68; died, May 8, of pulmonary tuberculosis.
- Peter Conway Kelley**, Grand Island, Neb.; Barnes Medical College, St. Louis, 1898; at one time member of the state legislature; aged 68; died, May 17, of heart disease.
- James Rufus Brown**, Spartanburg, S. C.; Baltimore Medical College, 1892; aged 71; died, May 25, in the Spartanburg General Hospital of cerebral arteriosclerosis.
- Bertrand M. O'Brien**, Danville, Ind.; St. Louis College of Physicians and Surgeons, 1903; formerly county coroner; aged 58; died, May 1, of pulmonary tuberculosis.

DEATHS

JOUR. A. M. A.
Aug. 12, 1939

Robert River Robertson, Portsmouth, Va.; College of Physicians and Surgeons, Baltimore, 1887; aged 77; died, May 24, in the Norfolk (Va.) General Hospital.

Philip Henry Holmes, Tarpon Springs, Fla.; University of Illinois College of Medicine, Chicago, 1903; formerly a practitioner in Chicago; aged 69; died, May 5.

Ralph Vorhees Murray, Roanoke, Ind.; Jefferson Medical College of Philadelphia, 1904; served during the World War; aged 57; died, May 6, of angina pectoris.

Edward Gilbert Cox, Gilbertsville, N. Y.; Albany Medical College, 1893; for many years police surgeon in Albany; aged 71; died, May 5, of coronary thrombosis.

William M. Campbell, Tulsa, Okla.; Missouri Medical College, St. Louis, 1890; member of the Oklahoma State Medical Association; aged 77; died, April 21.

Frederic Leroy Kellogg, Boston; Bellevue Hospital Medical College, New York, 1889; member of the Massachusetts Medical Society; aged 71; died, May 2.

James H. Logan, Lebanon, Okla.; University of Tennessee Medical Department, Nashville, 1892; member of the Oklahoma State Medical Association; died in May.

Charles Catlin Partridge, Melrose, Mass.; University of the City of New York Medical Department, 1883; aged 80; died, May 29, of cerebral hemorrhage.

David Joseph Mahan, Santa Rosa, Calif.; University of California Medical Department, San Francisco, 1906; aged 62; died, April 29, of coronary occlusion.

H. Will Elders, St. Joseph, Mo.; American Medical College, St. Louis, 1894; aged 65; died, April 23, in a hospital at San Francisco of arteriosclerosis.

Domitilo Rodarte, El Paso, Texas; Universidad Nacional Facultad de Medicina, Mexico, D. F., 1901; aged 65; died, May 31, of bronchogenic carcinoma.

Ralph McDaniel, Waco, Texas; University of Texas School of Medicine, Galveston, 1898; also a druggist; aged 68; died, May 9, of combined sclerosis.

Arden Pascal Kessler, Dayton, Ohio; Ohio Medical University, Columbus, 1893; aged 70; died in April of arteriosclerosis and cerebral hemorrhage.

May C. Walker, Santa Cruz, Calif.; Kansas City (Mo.) Hospital College of Medicine, 1886; aged 80; died in April of heart disease and arteriosclerosis.

Mary Elizabeth Bliss, Utica, N. Y.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1896; aged 70; died, April 24, of coronary thrombosis.

Emile Oswald Voyer, Los Angeles; Medical Department of Hamline University, Minneapolis, 1906; aged 64; died, April 13, of chronic myocarditis.

George Byron Hyde, Wilmington, Vt.; Atlanta Medical College, 1890; served during the World War; aged 76; died, May 17, of coronary thrombosis.

Roy Samuel George, Atlanta, Ga.; Atlanta Medical College, 1910; aged 49; died, May 5, of acute dilatation of heart and cirrhosis of the liver.

Samuel Peskin, New York; University of the City of New York Medical Department, 1898; aged 65; died, May 22, of coronary artery thrombosis.

Herman L. Nietert, St. Louis; St. Louis Medical College, 1889; member of the Missouri State Medical Association; aged 73; died, May 9, of pneumonia.

Frank S. Wright, Salmon, Idaho; Willamette University Medical Department, Salem, 1887; formerly state senator; aged 75; died, April 19, of senility.

McClelland Shellman, New York; University of Minnesota Medical School, Minneapolis, 1934; aged 30; died, May 5, in the Presbyterian Hospital.

Frederick Wach, Salt Lake City; Illinois Medical College, Chicago, 1908; aged 69; died, April 14, of myocarditis and hypertrophy of the prostate.

Frederick C. Crawford, Toledo, Ohio; Cleveland Medical College, 1897; aged 65; died, May 8, in Negley of otitis media and streptococcal septicaemia.

William Warren Tooker, Wichita, Kan.; Fort Wayne (Ind.) College of Medicine, 1891; aged 80; died, April 8, of carcinoma of the stomach.

Frederick Wallace Putnam, Binghamton, N. Y.; University of the City of New York Medical Department, 1880; aged 82; died, May 2.

William A. Marshall, Wharton, Ohio; Starling Medical College, Columbus, 1898; aged 73; died, May 8, in the Home and Hospital, Findlay.

John Randolph Comer, Hillsboro, Texas; University of Maryland School of Medicine, Baltimore, 1892; also a minister; died, April 27.

Jesse Wallace Powell, Millen, Ga.; Meharry Medical College, Nashville, Tenn., 1918; aged 48; died, May 18, of cerebral hemorrhage.

George T. Love, Wenona, Ill.; Hospital College of Medicine, Louisville, Ky., 1897; aged 66; died, May 1, in St. Mary's Hospital, Streator.

H. D. Ford, Chicago; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1874; died in May of injuries received in a fall.

Joseph R. Burchell, Manchester, Ky.; University of Louisville Medical Department, 1877; aged 88; died, May 24, of lobar pneumonia.

Norbert Rieser, New York; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1921; aged 43; died, May 3.

Albert Roy Bickstein, Philadelphia; Medico-Chirurgical College of Philadelphia, 1905; aged 54; died, April 27, in the Jeanes Hospital.

George Henry Calkins, Buffalo; University of Buffalo School of Medicine, 1893; aged 76; died, May 12, of carcinoma of the prostate.

Herbert Henry Thompson, Minneapolis; Jefferson Medical College of Philadelphia, 1909; aged 55; died, May 22, in Fort Snelling.

Harry Albertus Brown, Whitinsville, Mass.; University of Vermont College of Medicine, Burlington, 1895; aged 67; died, May 7.

John Collins Leever, Defiance, Ohio; Miami Medical College, Cincinnati, 1880; aged 84; died, May 13, of carcinoma of the stomach.

Harry Homer Dally, Chicago; Rush Medical College, Chicago, 1902; aged 60; died, May 20, in Kempton of cerebral hemorrhage.

William Ellsworth Barnes, Boston; Boston University School of Medicine, 1893; aged 77; died, May 5, of coronary thrombosis.

Locke Harwood Bugbee, Putney, Vt.; Dartmouth Medical School, Hanover, 1902; aged 65; died, May 24, of coronary occlusion.

Willis Bryant Moore, San Diego, Calif.; Halifax Medical College, Dalhousie, N. S., Canada, 1879; aged 83; died, April 13.

Frederick James Hosking, Hillsdale, Ont., Canada; University of Toronto Faculty of Medicine, 1934; aged 33; died, May 14.

William Jeter Quinn, Dallas, Texas; Barnes Medical College, St. Louis, 1896; aged 65; died, May 23, in the Baylor Hospital.

James Massie Gleason, Amonate, Va.; Medical College of Virginia, Richmond, 1932; aged 32; died, May 25, of heart disease.

Thomas C. Hainline, Seaton, Ill.; Keokuk (Iowa) Medical College, 1897; aged 81; died, May 19, of an injury received in a fall.

Willis Monroe Hunter, Van Wert, Ohio; Baltimore Medical College, 1892; aged 72; died, May 21, of cerebral hemorrhage.

James Clay Ross, Marion, Ind.; Louisville (Ky.) Medical College, 1906; aged 61; died, May 3, of cerebral sclerosis.

Joseph F. Barton, Jasper, Ala. (licensed in Alabama in 1903); aged 68; died, May 20, of cirrhosis of the liver.

Willard E. Gant, Hardin, Mo.; St. Louis Medical College, 1884; aged 79; died, May 4, of a cerebral hemorrhage.

James Wilson Edgar, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, 1891; died, May 7.

John Wylie Anderson, Denver; Hahnemann Medical College of Philadelphia, 1882; aged 81; died in May.

Joseph M. B. Johnson, Birmingham, Ala.; Miami Medical College, Cleveland, 1883; aged 81; died, April 29.

John Jerome Anderson, Brooklyn; Long Island College Hospital, Brooklyn, 1911; aged 54; died, May 30.

Andrew Brown, Markdale, Ont., Canada; University of Toronto Faculty of Medicine, 1902; died, May 3.

Charles B. Brewster, Eustis, Fla.; Pulte Medical College, Cincinnati, 1904; aged 62; died, April 24.

Alfred Olaf Peterson, Omaha; Omaha Medical College, 1899; aged 66; died, May 9, of leukemia.

Correspondence

SUBSIDIZED RESEARCH

To the Editor:—In Correspondence in THE JOURNAL July 15 Dr. J. A. Buchanan comments on the subsidized "researches" undertaken for the purpose of furnishing advertising propaganda.

Dr. Buchanan's letter echoes, I am sure, what many have felt but few, unfortunately, have bothered to express. As Dr. Buchanan says, "experience has demonstrated that too frequently the recommendations have been influenced by the subsidy."

It is indeed high time that the prostitution of the profession in this manner should be, as Dr. Buchanan suggests, recognized as a disgrace, declared unethical and suppressed. Certainly, if such "researches" and "clinical studies" are undertaken in good faith, there should be no reason to conceal the fact that they are subsidized or the amount of the subsidy and its source.

As it is, such practices are more malodorous than scientific, inspire neither respect for the "eminent authors" nor confidence in their observations, and tend, in the long run, to arouse grave doubts of the good faith of the sponsor broadcasting them ad nauseam.

R. A. KILDUFFE, M.D., Atlantic City, N. J.

RELIEF OF PAIN IN CHILDBIRTH

To the Editor:—Relative to the editorial "Relief of Pain in Childbirth" in THE JOURNAL June 24, may I remark that we introduced in the obstetric service of Johns Hopkins Hospital the rectal administration of sodium amytal in the fall of 1927. The late Dr. Whitridge Williams took particular interest in this new development and reported our observations in the sixth edition of his textbook of obstetrics, in 1931. Residents of various obstetric services in this country who visited our institution had the opportunity of watching patients under amytal analgesia. In an article in the September 1938 issue of the *American Journal of Obstetrics and Gynecology* on the intravenous administration of postpartum extract (page 524) I remarked: "In 1928, the rectal administration of amytal was introduced. Our observations of rapid cervical dilatation, considerable alleviation of pain, amnesia, regularity of uterine contractions have been confirmed by several investigators. The evidence now at hand shows that the postpartum oxytocic effect is not abolished in the parturient woman by amytal or nembutal twilight sleep."

J. I. HOFBAUER, M.D., Cincinnati.

FRACTURE OF THE SPINE COMPLICATING METRAZOL THERAPY

To the Editor:—An article published recently in THE JOURNAL (June 3, p. 2240) entitled "Fracture of the Spine Complicating Metrazol Therapy" by B. T. Bennett Jr. and C. P. Fitzpatrick made the statement that "the roentgenogram showed compressed fractures of the eleventh and twelfth dorsal vertebra. This was considered a rare and unfortunate occurrence, the first of its nature reported in the history of metrazol therapy" (p. 2241). On page 2243 it was stressed that "this preliminary report directs attention to a previously undescribed condition, compressed fracture of the vertebra resulting from metrazol convulsive therapy."

Historically, credit should be given to an article by Harry Stalker which appeared in the *Lancet*, Nov. 19, 1938, page 1172, in which "a double vertebral compression fracture from convulsive therapy" was reported. This paper was abstracted for the *Archives of Neurology and Psychiatry* by me, the substance of which is as follows: Following the second convulsion brought about by 1 cc. of triazol, a man aged 25 with paranoid schizophrenia complained of severe pain in the back and was unable to move. Examination revealed localized tenderness and

a deformity over the sixth and seventh thoracic spines with no neurologic signs. X-ray examination revealed compression fracture of these two vertebrae. With the exception of dislocation of the jaws of patients, this was the only accident encountered in a series of fifty patients treated with convulsive therapy.

CHARLES M. KRINSKY, M.D., Boston.

BASAL METABOLISM TESTS

To the Editor:—A common method of connecting the patient to apparatus for a basal metabolism test is by means of a rubber mouthpiece. The nose is closed by means of a nose clip. With some patients this works very well but with many patients with large or irregularly shaped nostrils the clip has to be made extremely tight and set just so or a leak occurs.

The apparatus may provide a shiny metal mirror for testing for leaks, but after the nose clip is adjusted the patient may wrinkle the nasal muscles and change the position of the clip sufficiently to cause a leak to occur again.

This leak invariably causes a "high" reading. Also a tight nose clip gives the patient as much discomfort as any other part of the procedure, if not more.

The following simple addition to this procedure will prevent this leakage: Before the nose clip is fitted, the vestibules of the nose are filled with a firm, nonirritating ointment. Boric ointment is satisfactory, an amount the size of a pea being used in each vestibule, after which the nose clip is placed on the nose with but little tension. It is not necessary to bring the edges of the vestibule together. If the patient then wrinkles the nose or changes the position of the clip, the ointment will retain the seal. The excess ointment may be wiped off and the smooth appearance of the ointment will give visual evidence of the seal.

H. W. SEIGER, M.D., Ocean Park, Calif.

DETERMINATION OF PROTHROMBIN

To the Editor:—In this column there recently appeared a note by Dr. Armand J. Quick dealing with prothrombin tests as applied to the control of vitamin K therapy (June 17, p. 2552). One such test, advocated by our laboratory, consists simply of mixing thromboplastin (a simple saline extract of lung) with whole blood and observing the clotting time (Ziffren, S. E.; Owen, C. A.; Hoffman, G. R., and Smith, H. P.: *Proc. Soc. Exper. Biol. & Med.* 40:595 [April] 1939). The clotting time is normally from twenty-five to thirty seconds but is typically prolonged when the prothrombin level is low. Dr. Quick objects to this test on the ground that clotting times cannot be measured accurately at the bedside. We have had no particular difficulty in this respect. A stop-watch is desirable, but even this is not essential, for an error of two seconds affects the result by less than 10 per cent.

The technic preferred by Dr. Quick is more complex, for in his test oxalated plasma is recalcified and then treated with thromboplastin. A centrifuge and water bath are needed. The amount of calcium added is arbitrary and the clotting mixtures are hypotonic. We have found that this affects the test.

In the article cited we have shown that both Quick's test and the bedside test are affected by factors other than the prothrombin level. However, careful analytic work has shown that in vitamin K deficiency a prothrombin deficit does exist and is the essential cause of the bleeding which occurs. Under these restricted circumstances either of these tests will give an accurate index of the tendency to bleed. The bedside test avoids many of the theoretical difficulties inherent in the technic of Quick, in addition to having the practical advantage of extreme simplicity. It thus seems to be the method of choice for control of vitamin K therapy in clinical work.

The question of priority for the bedside test is somewhat academic. The mixing of blood and thromboplastin is a very

QUERIES AND MINOR NOTES

Jour. A. M. A.
Aug. 12, 1939

old experiment, and of course neither Quick nor we can claim priority for that. All of his experiments with thromboplastin and whole blood were in cases presenting normal prothrombin levels. His belief that low prothrombin levels would be detected by such a test was an assumption for which he provided no data. Our own studies appear to be the first in which thromboplastin was actually used to test the blood of patients low in prothrombin.

H. P. SMITH, M.D., Iowa City.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VENETIAN BLINDS AND EYESTRAIN

To the Editor:—During the past few years so many cases of defective vision and eyestrain have been brought to my attention wherein the cause has been traced theoretically by me to Venetian blinds, that I am most curious to know whether there are any statistics or literature on this subject. The general symptoms seem to start with a "sort of wavering of the vision for a few moments before clear focus is achieved," and all complain of strain across the forehead, just at the level of the brows, as though it was necessary to narrow the vision horizontally in order to see clearly. This of course was the basis of my theory of the Venetian blind factor. In every instance in which such symptoms have been expressed the patient was using Venetian blinds either in the home or in the office. I have questioned every one among my acquaintance using Venetian blinds, aside from those with a disorder of the eyes, and have received the same report from all, that Venetian blinds cause an optical illusion of wavering, until proper focus is adjusted, and after looking through them the retina retains the picture of the slats for some time and even occasionally when the vision is changed from distance to close or vice versa. This may prove interesting.

M.D., California.

ANSWER.—The after-image produced by looking through Venetian blinds must be of the same basic value as that produced by looking through any other medium which obstructs all or part of the field of vision. After-images vary of course in intensity, but those produced through contrast between bright daylight (as seen between the slats of a Venetian blind) and the slats themselves must be of minor intensity, as after-images of the ciliary muscle can scarcely result from such contrasting images. A more likely source of distress would be fatigue of the ciliary muscle in its attempt to adjust the curve of the lens to focus on any unusual object in the field of vision. But here also the stimulus would appear to be too weak to produce fatigue of a ciliary muscle which was otherwise meeting all demands made on it. The possibility of coincidence of a refractive error needing correction and the use of Venetian blinds is of course great.

Positive and negative after-images of windows were described by Peirese in 1634, and the rather extensive subsequent bibliography can be found in Helmholtz. This whole question is dealt with rather fully (except that the phrase "Venetian blinds" was not then known) in Helmholtz's *Physiological Optics*, the first edition in 1866 and the third edition in 1909. This was translated by the Optical Society of America into English and published in three volumes in 1921. The material in question appears in the second volume, pages 172 to 299.

SODIUM THIOCYANATE IN HYPERTENSION

To the Editor:—Could you give me any information or cite references concerning the pharmacologic action and advisability of the use of sodium thiocyanate in hypertension?

M.D., Michigan.

ANSWER.—The first recorded studies on the pharmacology of the thiocyanates were those of Pauli in 1903 (*München. med. Wchnschr.* 50:153 [Jan. 27] 1903). Westphal (*Ztschr. f. klin. Med.* 101:545, 1925) made the first extensive clinical investigations in 1925. Since then medical literature has contained a great many reports. The exact pharmacodynamics of the thiocyanates is not yet fully understood; it is presumed that they act directly on the arteriolar musculature in diminishing hypertonus. A complete bibliography is beyond the scope of this reply.

Sodium or potassium thiocyanate is an effective vasodilator, but the salts are toxic. The margin between toxic and clinically effective doses is close.

Much of the literature deals with the therapeutic results obtained in series of cases of hypertensive arterial disease and the frequency with which toxic manifestations appear. The usual dose is from 0.3 to 1.0 Gm. a day in divided doses. The symptoms of poisoning have been previously discussed in this section of THE JOURNAL (Queries and Minor Notes, Feb. 24, 1934, p. 637). In 1936 Barker (*THE JOURNAL*, March 7, 1936, p. 762) instituted closer control of his patients on thiocyanate medication by frequent analyses of the thiocyanate content of the blood. By maintaining a blood concentration of from 6 to 12 mg. per hundred cubic centimeters of blood he was able to avoid precarious intoxications and yet obtain the maximum hypotensive activity of the drug. Individual susceptibility has an important part in the which renal elimination is impaired, thiocyanate should not be prescribed unless such control is included in the management. O'Hare and his co-workers (Massie, Edward; Ethridge, C. B., and O'Hare, J. P.: *New England J. Med.* 219:736 [Nov. 10] 1938) have emphasized the urgent desirability of making the blood analyses at frequent intervals. This can be done with relative ease, since Griffith and Lindauer (*Am. Heart J.* 14:710 [Dec.] 1937) introduced a micromethod for measuring the thiocyanate content of the blood in 1937. Although the analytic measures employed are by no means highly sensitive, they are sufficiently accurate for most clinical purposes.

ELECTRIC ARC WELDING AND IMPOTENCE

To the Editor:—Have you any information regarding impotence in males who are engaged in electric arc welding? A patient of mine, aged 36, is unable to have an erection; the condition has been present about six months and began shortly after he began doing arc welding. Complete physical examination, the Kahn reaction and examinations of blood and urine are negative. His diet and his domestic relations are above the average. There is no history of gonorrhea and there are no signs of prostatic disease. The testes are of normal size and are not tender. Secondary sex features are normal. This man has been using gasoline that contains tetra-ethyl lead to wash his hands and for other cleaning operations on machinery. Would this cause his trouble?

Phillip V. Dreyer, M.D., Huntsville, Mo.

ANSWER.—At one time or another most occupations have been suspected of being a factor in sexual impotence. In a recent inquiry within the dry cleaning industry, the most frequent complaint against chlorinated hydrocarbons was that they caused impotence. When recently one manufacturer provided sodium chloride tablets for the prevention of sodium chloride fatigue, indignant protests were made by workers that the management was providing a sexual sedative. Such suspicions endlessly recur in industry, and on occasion a few have been dignified by medical publications. Lately apprehension has arisen lest working within the electrical field of the ultra high frequency short wave radio-casting equipment might cause impotence and sterility in both males and females. Since in this field of work it is possible that multiple electrical fields may be set up in body organs, these claims cannot be laid aside as preposterous. They are, however, unproved. With regard to electrical welding, Holstein in 1930 (*Zentralbl. f. Gewerbchyg.* 7:286, 1930) claims that electrical welding is capable of harm to genital functions owing to structural damage to testicular tissues. Also welding has been associated with impotence in a Russian publication by Yakobson in 1935 (*Effect of Electrical Welding, Sovet. vrach. gaz.*, p. 1771, Nov. 30). Without denying the possibility, it may be pointed out that in arc welding various oxides of nitrogen and heat. Not one of these exposures is known to be capable of producing sexual impotence as the sole manifestation. The fact that nitrogen compounds may be produced in arc welding may be the basis for the belief that that some inorganic nitrogen compounds constitute sexual sedatives. Whenever any debilitating occupational disease arises such as lead or benzene poisoning, sexual capacity may be diminished or temporarily disappear. The same would be true in nonoccupational diseases such as typhoid or pneumonia. It may be definitely stated that impotence will not arise as the sole and exclusive manifestation of any occupational disease, with the possible exception of damage from roentgen rays.

It is well known that one action of lead and lead compounds, both in human beings and in the lower animals, is to damage sexual tissues and to promote sterility, abortions, miscarriages and the like. It is to be believed, however, that this will not arise in the absence of other and more characteristic features of lead poisoning. There exists scant evidence, if any, that

the nitrogen compounds produced in welding will exert any direct or primary action other than on the respiratory tract. Functional impotence is distinctly related to the individual. The fundamental causative factors are emotional and psychologic. In the absence of demonstrable organic disease, patients with impotence, if needing any investigation and treatment whatever, usually prosper best when guided by psychiatrists.

DERMATITIS FROM PITCH

To the Editor:—A patient employed as a roofer has had his face exposed to the fumes of hot pitch. Petrolatum, ordinarily used as a prophylactic on the face, had been neglected. The face shows hairlike parallel cracks on the epidermis of the exposed parts except for the nose, which shows only redness and edema. Since this is the first case I have seen, I should like to know more about pitch fume dermatitis, which I presume it to be.

Hubert C. Miller, M.D., Racine, Wis.

ANSWER.—Dermatitis and melanosis are not of unusual occurrence among workers exposed to the fumes or dust of coal tar distillates, especially coal tar pitch. Sunburn and melanosis are caused by the photosensitizing effect of coal tar derivatives on the skin. Some workers exposed to these substances burn more easily and more severely than normal persons, while in others melanosis develops. Sensitivity to some of the constituents of coal tar would also cause an urticarial dermatitis of the exposed parts.

Occupational keratoses, papillomas and epitheliomas may also be caused by long exposure to coal tar products.

Distillers of coal tar, roofers, road makers, briquet makers, fiber conduit makers and those engaged in preserving wood with creosote oil are some of the workers exposed to these skin hazards.

This subject is discussed more fully by Harry R. Foerster and Louis Schwartz (Occupational Melanosis from Pitch, *Arch. Dermat. & Syph.* 39:955-968 [June] 1939; Industrial Dermatitis and Melanosis Due to Photosensitization, *ibid.* 39:55-68 [Jan.] 1939).

DECREASED INSULIN REQUIREMENT IN THE DIABETIC

To the Editor:—Is it true that a few diabetic patients, even though they are considered to have the disease in a severe form, are either cured of the disease later in life or can cut down on their insulin a great deal? This question was asked by the husband of one of my patients who has diabetes in a severe form. I could not answer him as to whether or not it was true or false. The patient developed diabetes in 1924 at the age of 12 years and has been taking insulin in large amounts ever since. In January 1938 she went into coma and after she was brought out of it she was put on a regimen of 15 units of ordinary insulin before breakfast and 65 units of protamine zinc insulin at 11 o'clock in the morning. She also was on a diet and this she adhered to faithfully. She got along fine on this amount of insulin until October 1938, when she developed an insulin shock during the night. Dextrose was given intravenously and she recovered. I then had her test her urine at bedtime and had her cut insulin down to 43 units at 11 a. m. but the other night she had a mild insulin reaction. She is also at times having mild reactions in the morning about four hours after taking the regular insulin. I have given instructions to cut that down 2 units at a time and to test the urine four hours later. The patient has been on the same diet that she started in January 1938 and weighs about the same as she did at that time. She has not been working any harder than she did a year ago either. However, she was married shortly before she began to have trouble with her insulin dosage. She is not pregnant. An answer to this inquiry would be greatly appreciated by the patient and me if it is possible for you to do so.

M.D., Iowa.

ANSWER.—Few physicians wish to risk their reputations by stating that persons with diabetes are cured because, although patients advancing in age with the duration of their diabetes may show little or no glycosuria and no hyperglycemia under ordinary conditions, yet in the presence of infection the diabetes again becomes active. It is true that some patients are enabled to reduce the quantity of insulin. This is more apt to occur in the young during the years following adolescence and among older persons. It is a common observation that patients entering a hospital with an infection may require large doses of insulin but in the course of a few weeks under the influence of dietary treatment or subsidence of infection or both may require little or no insulin even with a liberal diet.

As for this patient who developed diabetes in 1924 at the age of 12 years and has depended on 80 units of insulin (15 regular and 65 protamine), it is not surprising that she should have improved and have had an insulin reaction. For such cases it usually is wise regularly to give carbohydrate not only in the latter part of the forenoon and afternoon, but on retiring a little protein and fat in addition, such as cottage cheese or

a few nuts to prolong the absorption of the carbohydrate. One should give the luncheons always and not alone when the urine is sugar free and plan the insulin accordingly. Apparently marriage agrees with the patient. Life may be more uniform, the diet may be more appropriately carried out and slight changes in times of meals and exercise may have contributed to the good results, even apart from happiness.

It would be worth while to try the effect of giving the two types of insulin by separate injection in the morning before breakfast with no more insulin during the rest of the day. Then two tests of urine become important in the subsequent regulation of dosage: (1) the test of a specimen before breakfast (not the overnight specimen), which indicates the effect of the protamine zinc insulin given on the previous morning, and (2) the test of a specimen voided just before the noon meal, which indicates the effect of the regular insulin taken on that day. Changes in either or both types of insulin may be made 2 or 4 units at a time, two or three days being allowed between changes.

ALUMINUM PAINT AND THE EYES

To the Editor:—What effect will the spraying of aluminum paint have on the eyes and, if any, what is the prophylaxis and treatment? I understand that this paint is made by mixing aluminum with a cheap grade of varnish. Please give me what information you have on this subject.

M. E. Rust, M.D., Pawhuska, Okla.

ANSWER.—Powdered metallic aluminum possesses no chemical properties detrimental to the eyes. Mechanical injury might arise, just as from any other solid ingredient of paints. Liquid vehicles for aluminum paint may be more damaging to the eyes. In earlier days, aluminum powder was suspended in lacquer types of menstrooms with amyl acetate (banana oil) as the commonest ingredient. At the present time, some aluminum paints are still so made. Vapors from these lacquers are well known causes of minor degrees of conjunctivitis. Better grade aluminum paints utilize different vehicles, depending on the purposes for which the coating is supplied. For automobile motors and similar metal equipment an ester gum varnish now enjoys wide use. For outdoor purposes the vehicle represents a synthetic resin varnish.

Numerous different solvents may enter these varnishes, including toluene, naphthas, turpentine and at times alcohols. Any one of these divers substances, in addition to possible effects elsewhere, may cause conjunctivitis on direct contact with the eyes and many may induce mild conjunctivitis on contact with their vapors. However, the low order of irritation from the vapors of aluminum paint ordinarily calls for no special prophylactic measures. When the work is continuous, spraying should be carried out only in booths. Either water or air carriage type of booths properly constructed and operated never be performed in small closed-off spaces, such as the interior of a tank or a small room. Since the lacquer types of aluminum paints are more injurious than others, this variety should be avoided as a prophylactic measure. Positive pressure hoods with open faces are quite effective in warding off the deleterious action of this class of paint.

INSULIN REACTIONS AFTER BEE STINGS

To the Editor:—A diabetic patient is taking 51 units of insulin daily. During the last year his duties have included the care of ten hives of bees. It is his impression that his general condition has been much improved since taking over this new occupation. He has observed on numerous occasions that multiple bee stings are followed by an insulin reaction. In one instance, when a hive was upset and he was stung twenty-five or fifty times in one day he omitted 10 units of insulin from his regular dose, in spite of which he suffered a series of insulin shocks. Although the story sounds plausible when told by the patient, I wonder whether it has any scientific basis. Would you kindly let me know if there have been any previous observations of this sort?

Paul Geary, M.D., Plainfield, N. J.

ANSWER.—No information is available as to the possible effect of multiple bee stings on the blood sugar. Certainly one would demand that accurate data be supplied as regards the level of blood sugar before and after contact.

Is it not possible that the patient in question is more active physically at his new occupation than he was before and, because of this additional physical exertion, that he has obtained the customary beneficial effects of exercise as regards the control of his diabetes? Is it not possible also that, on the day on which he suffered from twenty-five to fifty bee stings, he was even more active than usual and that his bodily feelings were such that less food was consumed?

POSSIBLE INTERMITTENT CLAUDICATION

To the Editor:—A man aged 50, a bachelor of Italian birth, came to this country from the Italian Alps region in 1911. His chief complaints are cramps, pain and weakness in the muscles of the calves of the legs on walking short distances (one or two city blocks at times, whereas at other times he is able to walk considerably farther without trouble). On these occasions he says that his back also becomes weak and tired but not sore. On mild exertion, such as shoveling snow, he also gets the symptoms. When he writes a few lines, the muscles of his hands also become weak and tired and he may have difficulty in adducting the fifth finger of his left hand. On arising in the morning he has difficulty in buttoning his clothes while dressing, owing to weakness and awkwardness in the use of fingers, but this improves in a few hours. He states that he has had these symptoms all his life as long as he can remember. He says that his older brother had the same condition. This brother served in the World War but died shortly after being mustered out of the Italian army. The patient himself remembers that at the age of 20, while in service in the Italian army, he could never walk or march long distances. He always had to drop out of line and quit with weakness because he just couldn't go any farther, while his colleagues all kept marching along. He saw brief service in the World War at Camp Grant, Rockford, Ill., but was shortly discharged because of this persistent inability to walk longer distances. He has never been able to work hard because of this condition and therefore was never able to earn enough to marry and support a family. He ekes out a meager existence running an automobile parking lot. He has observed on occasions that if he drinks a glass of beer it produces a remarkable change in his powers of endurance. On such occasions he can walk for many blocks without any evidence of fatigue, and though he doesn't like alcohol, he does drink a little occasionally whenever it is necessary for him to walk far. Formerly he smoked five or six corncob pipefuls of tobacco a day and one or two cigars but he has not done this in recent years. Otherwise the history and the physical and neurologic examinations are negative. The blood count is normal and urinalysis and the Wassermann reaction of the blood are negative. The condition looks like intermittent claudication, but all the peripheral arteries are patent and pulsate well, including the radials, tibialis posterior and dorsalis pedis arteries on both sides. There is also no muscular atrophy to suggest primary muscular atrophy or dystrophy. He has been examined by many different physicians both in this country and in Italy over a period of many years, and no one has ever been able to make a diagnosis. The condition sounds to me like a congenital vascular arterial insufficiency with improvement after vasodilatation by alcohol. Could you suggest to me any other diagnosis or give me some ideas regarding treatment?

M.D., Milwaukee.

ANSWER:—The subjective complaints are compatible with a diagnosis of intermittent claudication, in all probability based on a congenital vascular abnormality of the peripheral blood vessel system. The fact that there is good pulsation in the peripheral vessels does not militate against a diagnosis of peripheral vascular disease. His weakness and awkwardness in the use of his fingers on arising may be due to a peculiar posture during sleep, causing pressure on an already abnormal vessel. It is not stated whether any of the tests have been done for patency of the vessels and for degree of possible vascular dilatation. These are the following: intradermal injection of histamine to determine the extent of flare formation; intravenous injection of typhoid vaccine to determine the degree of rise in temperature of the surface skin of the extremity; color changes in the dependent and elevated positions, and finally peripheral nerve block with cocaine. The latter differentiates organic from spastic occlusion. If significant changes are found one may inject tissue extract (vasodilator) two or three times a week or give some vasodilator drug by mouth. It is possible, if no abnormal changes are found with these tests, that the patient has myotonia congenita. If that is so, the giving of quinine hydrochloride 0.3 Gm. (5 grains) three or four times a day may effect improvement.

HORMONES IN DEAFNESS

To the Editor:—Kindly give me information or references concerning the treatment of deafness with hormones or glandular products. What is the opinion concerning their value?

M.D., Kentucky.

ANSWER:—Hormones and glandular products have been used in the treatment of deafness by various investigators and by several routes of administration.

Mortimer, Wright, Thomson and Collip of Canada have reported recently on the intranasal administration of estrogenic hormones in constitutional deafness (*Canad. M. A. J.* 40:17 [Jan.] 1939). This work was suggested by a study of cranial dysplasia, its presence in cases of constitutional deafness and a similarity in examinations of persons suffering from atrophic rhinitis. The deafness was of both the conduction and the perception type, and the audiometric records purport to show a statistically significant amelioration in the hearing level of the treated group. Despite this, the evidence appears unconvincing, especially if there was true otosclerosis or persons suffering from nerve deafness in the group studied. It seems unlikely that such a high percentage of cases presenting atrophic rhinitis should also present these specific hearing difficulties,

for such an association has not been noted by others. On the other hand, it is true that if the deafness in these cases was on the basis of a chronic catarrhal otitis media secondary to an atrophic rhinopharyngitis, treatment with estrogenic substances intranasally, as has been efficacious in atrophic rhinitis, would similarly be expected to help the hearing defect.

The treatment of otosclerosis by the intratympanic injection of thyroxine as first advocated by Gray and endorsed by Goldstein in this country must be also considered. It would seem that in some cases favorable results have been obtained. The method has not been widely accepted or adopted to date, however.

FORMOL-GEL TEST FOR RHEUMATIC FEVER

To the Editor:—Will you please describe the technic of the formol-gel test of Gaté and Papacostas?

M.D., New York.

ANSWER:—The formol-gel test may be performed as follows: To 1 cc. of serum in a test tube (8 mm. bore is a convenient size) add 2 drops of from 30 to 40 per cent formaldehyde, mix and allow to stand at room temperature. Normal control serums show no change in viscosity or transparency in twenty-four hours. With pathologic serums gelation, with or without opacity, may occur during this time. Following the suggestion of Gutman and Wise (*Proc. Soc. Exper. Biol. & Med.* 35:124 [Oct.] 1936), the results of the tests may be expressed as follows:

Gelation	Opacity
— = no increase in viscosity	— = no change
± = questionable increase in viscosity	± = questionable slight opalescence
+ = increased viscosity	+ = opalescent
++ = very viscous flow	++ = translucent
+++ = semisolid	+++ = semiopaque
++++ = solid	++++ = opaque

FIRST BREAST MILK

To the Editor:—Could you give me any information concerning the advisability or inadvisability of discarding the first breast milk obtained under sterile precautions by the use of an electric breast pump in a hospital following the birth of a child? Let it be taken for granted that the indication of the use of the electric breast pump is proper and advisable in the particular case and the patient either a primipara or a multipara. Many hospitals discard this milk.

M.D., Wisconsin.

ANSWER:—There is seldom any reason to discard the first breast milk obtained with a breast pump. Certainly this should not be done as a routine. The only time it is justifiable to discard the first or subsequent few specimens of milk obtained with a breast pump is when the mother is seriously ill or has been given large doses of drugs which are eliminated through the breast milk and which may have a harmful effect on the baby.

BIBLICAL REFERENCES TO MENSTRUATION

To the Editor:—Would you be so kind as to furnish me with information whereby I may locate passages in the Bible that refer to the function of menstruation?

Samuel C. Gwynne, M.D., Worcester, Mass.

ANSWER:—The following are the main places where menstruation is mentioned in the Bible: Genesis 31:35, 18:11. Leviticus 15:19-33, 18:19, 20:18. Ezekiel 18:6, 22:10. The passages in Leviticus are concerned with ritual uncleanness during menstruation and the prohibition of intercourse. Genesis 18:11 shows that the relation between the menopause and childbearing was known. For a general discussion of menstruation in Biblical and Talmudic literature see: Preuss, Julius: *Biblich-talmudische Medizin*, ed. 3, Berlin, S. Karger, 1923, page 138, and Brim, C. J.: *Medicine in the Bible*, New York, Froben Press, 1936, page 188.

GONADOTROPIC SUBSTANCE AND TUBERCULOSIS

To the Editor:—Please advise me whether the injection of gonadotropic substance from the urine of pregnancy for the treatment of oligospermia is contraindicated in a patient aged 28 with incipient tuberculosis.

M.D., Philippine Islands.

ANSWER:—The use of gonadotropic substance from the urine of pregnancy is not contraindicated in a patient suffering from incipient tuberculosis.

Medical Examinations and Licensure

COMING EXAMINATIONS
STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in The JOURNAL, August 5, page 531.

NATIONAL BOARD OF MEDICAL EXAMINERS
NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS
AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written.* Various places throughout the United States, Sept. 9. *Oral.* Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written.* Various large cities in the country, Oct. 9. *Applications must be received by the Secretary by Sept. 1. Oral.* Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Jan. 6. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).*

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* March 9. Formal application must be received before January 1. *Oral.* Chicago, Oct. 7 and New York, June 10. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. *Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.*

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., II meeting of the American Academy of Pediatrics. Chicago, June 10. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklm, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF SURGERY: *Part I (Written).* Simultaneously in various centers throughout the United States, Oct. 9. *Applications must be received by the Secretary not later than Aug. 15. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.*

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. (The only examination session to be held in 1940.) *Case reports must be submitted not later than November 9. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.*

Alabama June Examination

Dr. J. N. Baker, secretary, Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, June 20-22, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Thirteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)	80.7	
Louisiana State University.....	(1937)	89.9

Montana April Report

Dr. S. A. Cooney, secretary, Montana State Board of Medical Examiners, reports the written examination held at Helena, April 4-5, 1939. The examination covered ten subjects. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. Seven physicians were licensed by reciprocity and one physician was licensed by endorsement at the meeting held April 3. The following schools were represented:

Book Notices

Silicosis and Lead Poisoning Among Pottery Workers. By Robert H. Flinn, Passed Assistant Surgeon, United States Public Health Service, et al. From the Division of Industrial Hygiene, National Institute of Health. Prepared by direction of the Surgeon General. United States Treasury Department, Public Health Service. Public Health Bulletin No. 244. Paper. Price, 30 cents. Pp. 178, with 78 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

This bulletin records the results of a resurvey of the most prominent physical defects encountered among workers in pottery factories originally observed in 1919. The value of reports of this kind is exemplified in the degree of control which has been established in the interim over exposure to lead. Once a major hazard in the pottery industry and still a potential source of trouble, the problem is being solved by engineering methods and by substitution of relatively nontoxic glazes for those formerly containing soluble lead compounds. A good share of the medical and engineering studies refer to silicosis. The criteria for establishing a diagnosis are emphasized both clinically and radiologically. Valuable verifying data are provided by means of illustrative x-ray films and case histories, two necropsy protocols and reports on peritoneal response to injected dust samples in guinea pigs according to the method of Miller and Sayers. Several interesting three dimensional charts have been developed regarding positive chest conditions in relation to length of exposure and concentration of dust. One infers that concentrations of dust can be held below 4 million particles per cubic foot and if so reduction in the incidence of silicosis will parallel the past records regarding lead poisoning. The incidence of tuberculosis has fallen off about in the same proportion as the industrial population in general. In this study active cases were discovered but could not be verified by sputum examination. The appended bibliography appears to be well chosen and the makeup of the bulletin is aided by a good index.

Iodine Metabolism and Thyroid Function. By A. W. Elmer, M.D., Institute of General and Experimental Pathology, John Casimir University, Lwów (Poland). Cloth. Price, \$10. Pp. 605, with 23 illustrations. New York & London: Oxford University Press, 1938.

This book is material proof of the stupendous growth of the literature since 1895, when Baumann discovered iodine as a normal element of the thyroid. The contents are thoughtfully arranged in four chapters: (1) historical review, (2) methods of iodine determination, (3) physiology of iodine metabolism and (4) pathology of iodine metabolism.

The historical review is on the whole excellent but is open to the criticism of omission and unconscious distortion inherent in such efforts. One may reasonably doubt that Rabourdin's method as used by Chatin was capable of detecting 0.1 microgram of iodine or that Chatin's work, though of the greatest importance in retrospect, contemporaneously influenced the development of our knowledge of the biologic importance of iodine. The chapter on methods of iodine determination gives a complete and critical summary of the evolution of these methods. Sufficient detail is given to permit one to carry out the procedures for the examination of inorganic and organic substances. The sources of errors and dangers are well emphasized. In the chapter on the physiology of iodine metabolism one notes the absence of important names such as those of Murray, Howitz and Magnus-Levy, who through their clinical and physiologic studies greatly stimulated interest in thyroid chemistry. In some instances the wrong authors are given credit for observations. This must happen occasionally when great numbers of contributions are being summarized but should

not occur so frequently as in this book. For example, Holst (1928) is given credit for the thyroxine oversaturation theory of postoperative crises in exophthalmic goiter. In all essentials this was an old theory in 1905 and was reasonably discredited by 1910. The chapter on the pathology of iodine metabolism reviews the work on hypothyrosis and hyperthyrosis. It is doubtful whether much knowledge of the pathogenesis of hypothyrosis has been or will be gained from the study of iodine metabolism alone. In other words, iodine studies have about the same value as morphologic studies.

This book will be a valuable addition to any reference library because it brings together most of the laboratory and experimental literature dealing with the biologic importance of iodine. A complete table of contents makes reference to any particular topic easy, and sixty pages of carefully checked, complete bibliographic references is an item of major importance to any student.

The Control of the Circulation of the Blood. By R. J. S. McDowall, M.D., D.Sc., Professor of Physiology, University of London. King's College. With the assistance of G. E. Malcomson, M.D., Lt.-Col. I. M. S., and L. McWhan. Cloth. Price, \$22.50. Pp. 619, with 38 illustrations. New York, Toronto & London: Longmans, Green & Co., 1938.

This is the most complete review of the literature on the physiology of the circulation yet available, encompassing as it does about 6,000 items in the bibliography. The senior author has long been recognized as an authority in this field; consequently one is not disappointed to find that, in addition to reviewing literature, he has given a scholarly analysis of the evidence bearing on many of the salient problems. Despite the great mass of material included, if one bears in mind the title there need be no surprise on finding that many phases of circulatory physiology are not discussed in detail. Evidently the aim was to confine the work to those factors which control circulation and there is consistent adherence to the plan. One could wish for a somewhat more systematic arrangement of material and a more detailed index. Also there is frequent reference to certain authors without any hint as to the nature of their work or to its place in the general alignment of evidence.

The illustrations are well suited to bring out pertinent points, but it would have been desirable to have many others graphically presented in view of the high degree of concentration of the textual evidence. There is not much direct reference to clinical applications per se, but the lucid exposition leaves no serious gap to be bridged by the clinician. This book presents a wealth of source material and, despite the defects, is a praiseworthy addition to the literature, especially for the busy physician who needs a condensed source of authority.

Health at Fifty. Edited by William H. Robey. Cloth. Price, \$3. Pp. 299, with illustrations. Cambridge, Massachusetts: Harvard University Press; London: Oxford University Press, 1939.

The title fails to do justice to this excellent book, because it is too narrow. While the greatest emphasis is placed on health in the middle decades, the book is packed with information useful at any adult age. It is a compilation of chapters based on public lectures given by the faculty of the Harvard Medical School, a series of lectures which was inaugurated in 1907 and has been interrupted for only one year, 1919. There are eleven chapters dealing in turn with heart disease, blood pressure, weight control, cancer, rheumatism, the menopause, the eyes, vitamins, glands, the family medicine cabinet and mental health, plus a summarizing chapter by the editor. The material is well authenticated, well selected and well arranged. Unlike many compilations of lecture material in which each chapter is contributed by a different author, this book is not discursive and repetitious, which means of course that it comprises a good job of editing and correlating as well as a basis of fundamentally sound material. One wonders why consideration of the ears and hearing was not included, since this is a vital problem in the middle decades and beyond, as are pneumonia, bronchitis and the related infections of the respiratory tract, which also are omitted or treated incidentally to other subjects. Nephritis and diabetes receive only incidental attention, the latter in connection with glands and the former with blood pressure. The style is surprisingly constant in view of the fact that so many authors have contributed, but this is another

indication of careful editing. The language is probably simple enough for lay readers with a good education and a willingness to refer to a dictionary once in a while, but there are a number of passages which might better have been simplified and made less technical for the so-called average reader. The best chapter in the book from the point of view of presentation and general usefulness to the lay reader is the one dealing with self-medication and the family catch-all known by courtesy as the medicine chest. The book as a whole will certainly repay a careful reading. As a reference book it would have been improved by the addition of an index.

Evaluation of the Industrial Hygiene Problems of New Hampshire. By Frederick J. Vintinner, B.S., Industrial Hygienist. State of New Hampshire Board of Health. Division of Chemistry and Sanitation. Charles D. Howard, S.B., Director. Paper. Pp. 133, with 5 illustrations. Concord, New Hampshire, 1938.

This survey, which will be of greatest interest to physicians in New Hampshire, typifies the analysis of industrial hazards and present methods of control conducted recently by bureaus of industrial hygiene in a number of state health departments under the general guidance and stimulation of the United States Public Health Service. Sixty tables and the accompanying text present the character and extent of harmful exposures encountered by workmen in the area, including the availability of medical and nursing services, hospitalization, plant dispensaries, first aid arrangements and safety provisions in general. A series of recommendations is attached, sound and laudable for the most part but in which little mention is made of the possibilities for useful cooperation with organized medicine in the state or with individual industrial practitioners. This occurs in spite of a plea for better reporting of occupational diseases unattainable without considerable assistance from all types of physicians. Nevertheless the survey is useful not only as a catalogue of existing hazards but as a point of reference by which subsequent progress can be measured. It should be available to all physicians in the state in its complete form.

Report on Radium Beam Therapy Research 1934-1937. By Constance A. P. Wood, L. G. Grimmett, T. A. Green and others. Under the direction of the Governing Body of Radium Beam Therapy Research. Medical Research Council, Special Report Series, No. 231. Paper. Price, \$1.20; 4s. Pp. 77, with 36 illustrations including 22 plates. New York: British Library of Information; London: His Majesty's Stationery Office, 1938.

This report records the result of four years' research into the treatment of cancer by means of the rays from a large mass of radium situated at a distance from the patient, as contrasted with the more usual type of radium therapy, in which much smaller amounts, properly contained, are inserted by surgical operation directly into the tissues or applied close to the skin. The former method, first developed in France, Belgium, the United States and, more extensively, Sweden, has been referred to as "radium beam therapy" or "teleradium therapy."

In the work represented by this publication, treatment was restricted to cancer of the mouth, tongue, pharynx and larynx, relatively accessible to radium therapy. By reason of the superficial sites of the growths, the local effects of the radiation could be readily observed. The results compared favorably with those to be expected from surgical intervention and were obtained without any mutilation of the patients. However, it is necessary to mention that the patient with cancer undergoing radium beam therapy cannot expect to escape a period of some discomfort during and immediately after the treatment, because of the effect of the radiation on the mucous membrane and the skin. This unpleasant reaction is characterized by difficulty in swallowing, loss of taste and dryness of the mouth, all of which disappear gradually after completion of the treatment. In patients whose lesions are still operable the treatment has given encouraging results, comparing favorably with those to be expected from operation. Of those with advanced or inoperable cancer, a few can be rendered free from disease and the remainder afforded a fairly satisfactory degree of palliation.

One interesting fact demonstrated in the preliminary studies of this research committee is that the unit roentgen (r) is applicable to radium as well as to x-ray therapy, provided certain precautions are taken, and the roentgen is now established as the international unit for both radium and x-ray therapy. This is a valuable bit of knowledge, for it will permit interesting and informative comparisons with parallel clinical investigations in x-ray therapy.

In a brief review it is impossible to present even a short abstract of the valuable methods devised, instruments invented and special technical maneuvers perfected. The latter half of the book is filled with illustrations, many of them in color, showing the progress of the disease in various lesions of the head, neck and jaw in various stages of treatment.

Dermatitis and Coexisting Fungous Infections Among Plate Printers. By Paul A. Neal, Passed Assistant Surgeon, and C. W. Emmons, Senior Mycologist. From the Division of Industrial Hygiene and the Division of Infectious Diseases, National Institute of Health. Prepared by direction of the Surgeon General. U. S. Treasury Department, Public Health Service. Public Health Bulletin No. 246. Paper. Price, 15 cents. Pp. 55, with 8 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

This report represents a careful study of the incidence of dermatitis in a group of plate printers exposed to a variety of mycotic, bacterial, mechanical and chemical skin irritants, the latter including colored inks and certain solvents used for cleaning plates. Through application of the criteria of Sulzberger it was determined that the dermatitis was industrial in origin although no single cause could be universally assigned. The authors recommend thorough physical examinations periodically of all employees, with routine patch testing for applicants. Past methods of hand cleansing are particularly criticized and suitable emphasis is placed on the need for cooperation by the employees in order that proper personal hygiene may contribute to the reduction of cutaneous irritation.

Röntgendiagnostik des Chirurgen. Von Professor Dr. Otto Klingreen, Leiter der chirurgischen Abteilung des städtischen Krankenhauses Lüdenscheld. Paper. Price, 30 marks. Pp. 324, with 527 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

This edition presents the roentgenologic diagnosis of surgical conditions completely and in an easily readable form. The first chapter begins with an introduction to x-ray technic and familiarizes the surgeon with the properties of x-rays and the equipment of a diagnostic department. A brief description of the kymographic, tomographic and densographic methods follows. The last-mentioned method is a graphic presentation of the distribution of various densities of shadows in the form of curves and employs a photoelectric cell connected with a registering galvanometer. The second chapter treats of the localization of foreign bodies and offers a description of the calcifications and ossifications seen in roentgenograms; the third, with fractures and pathologic processes of bones and articulations; the fourth, with the examination of lesions of the internal organs of interest to surgeons, e. g. empyema of the chest, pulmonary tumors, diaphragmatic hernia, ulcers and tumors of the digestive tract, and pyonephrosis, and the fifth, with an explanation of special methods of examination such as arteriography, venography, contrast filling of articulations, hepatography, lienography and pneumoperitoneum.

The treatise is a thorough, comprehensive, well arranged and competent book. It has been written to meet the needs of the general surgeon and therefore avoids any subjects of a purely theoretical character. The features of conciseness and clearness of expression are prominent. From the typographic point of view the book is excellent, having been printed in an easy to read type and profusely illustrated with reproductions of roentgenograms. In spite of the small size of the illustrations, the details have not been lost. As a well trained surgeon should be able to read roentgenograms without depending entirely on the diagnosis of the roentgenologist, this unusually helpful book will make a place for itself in the medical world.

Der Operationskurs des Hals-, Nasen- und Ohrenarztes. Von Prof. Dr. H. Beyer und Prof. Dr. A. Selfert. II: Die Operationen an Nase, Mund und Hals. Von Prof. Dr. A. Selfert. Second edition. Paper. Price, 24.50 marks. Pp. 266, with 351 illustrations. Leipzig: Curt Kabitze, 1939.

For its size, this is a valuable book. There are numerous illustrations, including photographs of instruments, surgical conditions and anatomic details which make it exceedingly useful for the beginning specialist and for the postgraduate student. The text although brief is authoritative. For one interested in the point of view of the German school in the field of diseases of the nose and throat, the author presents a reliable treatise. However, because it varies so little from the first edition it should be called a reprint and not a second edition.

The Microscopical Study of Drugs. By Lillian A. Kay, B.Pharm., Ph.C., Lecturer in Pharmacognosy, Leicester College of Technology, Leicester. Fabrikoid. Price, \$4. Pp. 228, with illustrations. Baltimore: William Wood & Company, 1939.

Pharmacognosy as a separate branch of pharmacy has lost ground in schools of pharmacy during the last twenty-five years. Rarely is a pharmaceutical chemist nowadays called on to identify botanic drugs. This task is left to the expert possessing the necessary technical and practical experience. To demonstrate, however, to the pharmacy student the methods used in the microscopic study of drugs the author has selected a number of well chosen examples in the laboratory outline. In this way the student interested in pharmacognosy becomes acquainted with practical problems of the pharmacognosist. The text is clear and well suited for self study, but one might have wished for the inclusion of a list of larger reference compendiums to stimulate the more industrious student during his laboratory work.

Spring Floods and Tornadoes, 1936: Official Report of Relief Operations. ARC 979. Paper. Pp. 173, with illustrations. Washington, D. C.: American National Red Cross, 1938.

This official report of relief operations during the spring floods and tornadoes in 1936 is an attractive publication, well illustrated with maps, diagrams, photographs and charts, all dealt with in the modern, pictorial, statistical manner. There is a chronological report of developments presented as a typical picture of disaster situations and necessary relief. The manner in which relief was mobilized from all available sources is graphically described. Considerable space is given to rehabilitation of the physical damage and of the social damage. There is a chapter on medical problems too brief to be adequate, especially in view of the space given to other phases of disaster relief. There are extensive statistical reports in a series of appendixes. There is an adequate index. Though a paper binding is used, the printing and makeup of the book are exceedingly attractive, owing to the effective handling of illustrative matter and the large clear type and numerous subject headings.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Contracts to Pay for Medical Services Rendered by Physicians Selected by Corporation as the Corporate Practice of Medicine.—The state of California, on the relation of the state board of medical examiners, brought quo warranto proceedings against the Pacific Health Corporation to determine the right of the corporation to engage in the practice of medicine. From a judgment of the superior court, city and county of San Francisco, holding its activities violative of the medical practice act, the defendant corporation appealed to the Supreme Court of California.

The case was tried on an agreed statement of facts. The corporation was organized for profit under the general corporation law of California. On application of persons in good health, the corporation issued contracts by the terms of which it undertook, for a specified sum, to pay for services rendered to the holders of the contracts by physicians and hospitals and for certain other services. When a contract holder became sick or injured, the corporation advised him from what physician or hospital the services were to be obtained. After the services were rendered, the corporation paid the charges. The corporation kept a list of physicians and surgeons approved by it, and to obtain the benefits of the service the contract holders were required, except as to emergency expenses not exceeding \$50, to accept a physician from the list. The corporation advertised its service and solicited the public to purchase its contracts, paying commissions to its soliciting agents.

The defendant corporation admitted that a corporation may not lawfully engage in the practice of medicine but contended

that it did not undertake to perform medical services, only to furnish competent physicians; that the contracts did not contemplate that services were to be performed at the offices of the corporation but elsewhere, and that the physicians were not employed by the corporation on a salary basis nor directed by the corporation but were compensated for actual services after they had been rendered. The corporation's theory was that the physicians were independent contractors and that this fact absolved it of the charge of practicing medicine.

The Supreme Court was unable to agree that the policy of the law may be circumvented by technical distinctions in the manner in which the physicians are engaged, designated or compensated by the corporation. The evils of divided loyalty and impaired confidence, the court pointed out, seem to be equally present whether the physician receives benefits from the corporation in the form of salary or fees. Freedom of choice of physician is destroyed and the elements of solicitation of medical business and lay control of a profession were present whenever the corporation sought such business from the general public and turned it over to a special group of physicians. As was said in *Pacific Employers Ins. Co. v. Carpenter*, 10 Cal. App. (2d) 592, 52 P. (2d) 992:

But we need not quibble here over the use of terms, as it is immaterial whether the appointed practitioners are termed employees, agents, or appointees of the petitioner. The fact remains that petitioner's agreement was to furnish, in consideration of the premium paid by the insured, the services of doctors and dentists who were to be appointed, engaged, hired, or employed by petitioner for the purpose of furnishing such services. Any such agreement is clearly condemned as unlawful and against public policy . . .

The corporation stressed the effect that an adverse decision might have on other organizations and activities. The court's attention was directed to certain data from medical and lay sources in support of a movement for group medicine and health insurance, and the court was told that a decision against the corporation would outlaw all fraternal, religious, hospital, labor and other similar benevolent organizations furnishing medical services to members. The Supreme Court found this argument wholly unconvincing. The question of the effect of the decision on other organizations, the court said, was not squarely before the court and the information in the record as to their character and activities was meager and unsatisfactory. The court pointed out that the theory of applying the holding of the present case to such philanthropic associations as those mentioned apparently did not exist in the minds of the directors of such associations, nor had it been suggested that the public authorities contemplated any attack on them. This illusory apprehension was expressed, the court said, by the defendant corporation alone in an attempt to bolster up its case by bringing it within the general class of associations furnishing medical or health benefits which have been tacitly approved for generations. A most obvious and to the court a fundamental distinction must be made between the corporation and these other institutions. In nearly all of them, the medical service is rendered to a limited and particular group as a result of cooperative association through membership in the fraternal or other association, or as a result of employment by some corporation which has an interest in the health of its employees. The public is not solicited to purchase the medical services of a panel of physicians and the physicians are not employed or used to make profits for stockholders. In almost every case the institution is organized as a nonprofit corporation or association. Such activities, the court pointed out, are not comparable to those of a private corporation operated for profit, and since the principal evils attendant on the corporate practice of medicine spring from the conflict between the professional standards and the obligations of the physicians and the profit motive of the corporation employer, the objections of policy do not apply to nonprofit institutions.

The corporation questioned whether the time has come, as indicated by the movement for health insurance and group medicine, to reverse the long settled policy against corporate medical practice and declare it legal and proper. A simple answer would be, the court said, that the few extracts from the opinions of writers contained in the briefs furnished no evidence to the court whatever of a widespread change in

social point of view sufficient to repudiate the existing law of practically all the states. All that the court had before it was proof of a controversy between medical men, sociologists and others as to the future course of medical practice. The desirability of present methods and the suggested reforms, including various kinds of insurance and group treatment, have been hotly debated. Public policy may change, the court observed, and doubtless where statutes do not cover the field the court may follow such changes, but the court must in such case declare as the public policy the social view of people generally and not merely its own private choice among hopelessly conflicting views of desirable reform of settled practices or principles in the field. In the present circumstances, the court said, there can be no true declaration by a court that a change in social point of view now requires the abandonment of the rule against corporate practice of medicine. Such a drastic change should come from the legislature after the full investigation and debate which legislative organization and methods permit. Though certainly aware of the controversy, and with presumed knowledge of the court decisions of California preventing corporate practice, the legislature, the court observed, thus far has not acted.

The court observed, in conclusion, that an admission of the desirability of some form of health insurance or group medicine by no means requires approval of the activities of the defendant corporation. To the court it seemed perfectly possible to bring adequate medical service to the vast numbers of persons who now can ill afford it by some means which will protect both the profession and the public from the evils of corporate control of the practitioner.

The judgment of the trial court, declaring the activities of the corporation violative of the medical practice act, was therefore affirmed. A petition to the United States Supreme Court for a writ of certiorari was denied.—*People ex rel. State Board of Medical Examiners v. Pacific Health Corporation, Inc.* (Calif.), 82 P. (2d) 429; 59 S. Ct. 463.

CURRENT MEDICAL LITERATURE
Current Medical Literature**AMERICAN**

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Testing Fitness for Night Flying: Speed of Change of Adjustment of Eyes for Intensity of Light and Distance of Object. C. E. Ferree and G. Rand, Baltimore.—p. 655.

Frequency of Blinking as Criterion of Visual Ease.

Luckiesh and Moss discuss the periodic movements of the eyelids as a criterion of ease of seeing and as a clinical method for appraising ocular comfort. They have confirmed the assumption that blinking is associated with effort and fatigue by observing the frequency of blinking during the first and last five minute periods of an hour of continuous reading. The experimental conditions involved the reading of interesting material under three different levels of illumination by eleven adults possessing normal or near normal vision. The frequency of blinking was higher during the last five minute period of reading than during the first period under all illuminations. The rate of blinking during the last five minute period decreased as the task of reading was made easier by higher levels of illumination. Thus it appears that the frequency of blinking is definitely correlated with both the duration and the severity of the visual task. An increase in the frequency of blinking invariably occurs when the conditions for seeing are made more unfavorable, which involve (1) the fatiguing effects of prolonged voluntary activity of the extrinsic muscles, (2) the distraction of a bright peripheral image during reading, (3) the fixation and recognition of minute details, (4) an unusual relationship between accommodation and convergence owing to the red background of the reading matter and (5) perceptual and fixational difficulties arising from closely spaced lines of print. Hence it follows that the rate of blinking is intimately related to various and complex psychophysiologic factors involved in seeing, thus empirically confirming the conclusions of Ponder and Kennedy. Therefore blinking is an extremely sensitive criterion of ease of seeing and the authors have used it as a criterion for appraising ocular strain and fatigue arising from uncorrected or improperly corrected refractive errors of the human eye. The number of blinks occurring during five minute periods of reading is given for thirty subjects wearing plus 0.50 diopter spheres, plano lenses and minus 0.50 diopter spheres in addition to the usual correction, if any. The minimal frequency of blinking occurred with plano lenses in addition to the usual corrections, if any. Quantitatively, the frequency of blinking was increased about 42 per cent by the addition of the convex spheres and about 37 per cent for the concave spheres during a five minute period of reading. The highest rate of blinking was not obtained with the plano lenses in any one of the thirty cases studied. This fact represents additional evidence that the observed differences in blinking are due to differences in ocular comfort rather than to uncontrolled factors or chance.

Effect of Avitaminosis A on Blood.—Abbott and his co-workers made differential leukocyte counts on the blood of 157 individuals whose diets and symptoms indicated a vitamin A deficiency. The blood picture of all the subjects showed several variations from normal hematologic standards. Among these were a decrease in total leukocytes and polymorphonuclears, an increase in juveniles and large lymphocytes, and degeneration, especially of the granulocytes. This blood picture is similar to that of rats fed a diet deficient in vitamin A and, as in the case of the rats, the administration of large amounts of vitamin A brought about a gradual improvement in symptoms and in a few weeks the differential count was within the normal range. From this work it was concluded that the differential leukocyte count is of diagnostic value in vitamin A deficiency in man.

Landmann studied the nature of visceral involvement in 159 cases of tuberculosis of the bones and joints admitted to the Hospital for Joint Diseases and the Mount Sinai Hospital during 1932 to 1936 inclusive. Seventy-two cases involved the spine, forty-four cases involved the knee, eighteen cases involved the hip joints and twenty-five involved other joints. Ten of the 159 cases showed evidence of visceral complications. Most of the visceral complications were secondary tuberculosis infections or possibly foci present without symptoms before the onset of perceptible bone and joint manifestations. The complicating infection involved the genito-urinary system in eight

cases, the liver in one and Addison's disease was present in one. There were four cases of proved renal tuberculosis and one case of proved tuberculous epididymitis. The repeated demonstration of secondary genito-urinary involvement in skeletal tuberculosis should suggest the advisability of examining the urine of all patients suffering from tuberculosis of the bones and joints at regular intervals for tubercle bacilli, so that lesions might be discovered early. Since early renal tuberculosis gives no lead to the examiner because of lack of symptoms, repeated examination of the urine should be done as a routine. Many progressive cases of renal tuberculosis or tuberculosis of the ureter and bladder could be thereby anticipated and proper measures instituted.

Surgical Physiology of Duodenal Ulcer.—Burden believes that many of the clinical features of duodenal ulcer can be explained by the activity of the pyloric sphincter. It may cause the typical symptoms of ulcer when no ulcer is present, since the ulcer itself does not cause the symptoms which identify its presence. Dysfunction of the pyloric sphincter is one and hyperacidity is the other main factor in the etiology of duodenal ulcer. The normal stomach regulates its own acidity. Failure of this control means the development and maintenance of a duodenal ulcer. The pyloric sphincter because of spasm or failure to relax becomes a potent hindrance to the regurgitation of alkaline duodenal contents into the stomach. Of the two factors concerned in the etiology and maintenance of duodenal ulcer, dysfunction of the pyloric sphincter alone is amenable to direct attack. Its function can be abolished permanently by removing the anterior half of the sphincter without opening into the duodenum or stomach. This procedure has been carried out with lasting success in cases of duodenal ulcer.

Treatment and Prognosis of Tuberculosis in Children.

—Zacks observed the effect of treatment and prognosis, as measured by x-ray examination, on 536 children in the second decade of life with pulmonary tuberculosis who were followed for an average of four years. The most pertinent observation was that the treated boys give a mortality rate of 4.2 per cent a year, the untreated 3.2 per cent a year. The mortality for the treated girls is 7.1 per cent, for the untreated 5 per cent. This result can be explained only on the basis of selection, as the patients with a more advanced condition were naturally the first to accept treatment. The author's conclusions are that bed rest alone in a sanatorium does not modify the course of spreading tuberculous lesions to an appreciable degree and does not reduce the mortality from these lesions. Bed rest alone or bed rest with pneumothorax has not appreciably affected the mortality in advanced bilateral lesions or lesions of minimal extent that are allowed to progress too far without early collapse therapy. Collapse therapy in advanced unilateral lesions tends at least to prolong life and it may also reduce the mortality. Evidence seems to indicate that early collapse therapy may reduce the fatality rate of early asymptomatic lesions that show a tendency to spread. A final answer on this point cannot be given without at least five more years of observation. In

the second decade of life, the prognosis for soft early lesions is uncertain for at least ten years. Lesions that progress ultimately do poorly—those that retrogress on the whole do well. Retrogressive lesions should be observed by serial roentgenograms until definite stabilization is evident by calcification, by strandlike fibrosis or both.

Diabetes and Pulmonary Tuberculosis.—Root and Bloor assert, from a study of the various etiologic factors in 364 cases of diabetes with pulmonary tuberculosis, that the disturbed nutrition in diabetes is next in importance to contact with an open case of tuberculosis. Pulmonary tuberculosis developed in juvenile diabetic patients, whose diabetes began at or before the age of 20 years, more than twelve times as frequently as among pupils in the Massachusetts grade and high schools. Of seventy-three patients recovering from diabetic coma between February 1929 and November 1932, pulmonary tuberculosis developed in thirteen of them within five years. The incidence of pulmonary tuberculosis in adult diabetes does not show a decrease in rate corresponding with the general decrease in tuberculosis mortality in the community. Pulmonary tuberculosis followed the onset of diabetes in 83 per cent of the cases. The main features in 126 necropsies on diabetic patients with pulmonary tuberculosis were many healed foci, a tendency for the formation of tough, fibrous, pleural adhesions and a high frequency of caseating lesions with cavitation. Chemical analysis of the lungs of tuberculous patients with diabetes showed strikingly lower concentrations of phospholipid and lipid than in nondiabetic patients. Seven new cases of the diagnosis of tuberculosis in the minimal stage are reported. Among 258 fatal cases the average duration of diabetes to death has increased from 5.4 to 10.1 years and the duration of pulmonary tuberculosis from 2.7 to four years. Diabetic patients make excellent subjects for pneumothorax and thoracoplasty. Routine x-ray examination of every diabetic patient's chest is recommended.

Appendicocostomy in Treatment of Peritonitis.—During the last six or seven years, Reeves has performed a cecostomy or appendicocostomy in fifty-two of his worst cases of ruptured appendicitis, in most of which there was a general peritonitis. He has not employed this operation in cases of recent rupture although he knows of no contraindication for doing it in such cases, nor has he used it in any case in which there was a walled-off abscess. There were six deaths in the fifty-two cases, a mortality of approximately 12 per cent, which compares favorably with other statistics. All the cecostomies closed primarily in from two to three weeks except in one case, in which the fistula was closed two months later.

Z Incision for Relief of Scar Contractures.—Davis and Kitlowski state that the operative procedure of the Z plastic maneuver, based on the transposition of two triangular flaps,

is simpler than other methods for relaxing scar contractures. Tissues which would otherwise be discarded are advantageously utilized. The appearance of an area relaxed by this method compares favorably with that of other methods. Additional scarring of unscarred areas is avoided. Contractions can be permanently relieved by this method which would be difficult or not practical to correct by skin grafting. Satisfactory and effective relaxation can be accomplished in contracted scars with bridges, webs or grooves. The suture line after transposition is as a rule Z shaped, but the Z is turned through approximately 90 degrees and the central line of the original Z lies transversely across the line of the scar pull and prevents recontraction. The success of the method depends on the presence of lax tissue which can be drawn in from the sides. In many instances the authors have been able to restore function and return patients, either partially or completely incapacitated, to their ordinary occupations. They have used the incision for many years on every part of the body and they find it one of the most generally helpful maneuvers.

Staphylococcal Septicemia.—Mendell discusses a series of thirty-five cases of staphylococcal septicemia seen over a period of eight years. There were six recoveries, twenty-nine fatalities and sixteen postmortem examinations. The incidence, sex, age, source of infection, duration of the disease, laboratory observations, complications observed clinically as contrasted with those seen at postmortem study, treatment and prognosis are discussed. It is shown that complications occur early in the course of the disease and exist more frequently than can be discovered clinically. With no specific treatment available, surgical eradication of the source of infection, with prompt removal of metastatic foci of suppuration as they occur, plus repeated immunotransfusions is the basis for any successful treatment. Three cases in which recovery was obtained are reported in detail to emphasize these features of the disease.

Excretion, Saturation and Utilization of Ascorbic Acid.—According to Spellberg and Keeton, persons normal from a dietary point of view show a prompt rise in urinary excretion and blood concentration of ascorbic acid, with rapid "saturation" when large doses of the acid are administered by mouth. "Exhausted" patients show a delay in saturation, but their blood concentration rises above 1 mg. per hundred cubic centimeters of blood before a great rise in the urinary excretion occurs. The diagnostic features of scurvy seem to be a lowered renal threshold for ascorbic acid, extreme depletion of the body stores and an unusual delay of saturation as evidenced by urinary excretion. There seems to be increased utilization of ascorbic acid in diseases accompanied by increase in oxidative processes or in cellular proliferation, e. g. (1) malignant tumor, (2) hyperthyroidism and (3) leukemia. Alkali medication does not interfere with absorption of ascorbic acid in cases of peptic ulcer. Treatment by Sippy diets when prolonged leads to

depletion of the stored ascorbic acid. Patients with clinical asthma show no abnormality of storage. Large doses of ascorbic acid given intravenously or by mouth have no ameliorating effect on the attacks. Hepatic damage in portal cirrhosis does not interfere with the storage of ascorbic acid. Ascitic fluid contains the same concentration of ascorbic acid as blood plasma.

Aneurysm of Vertebral Artery. P. Bassoe, Chicago.—p. 127.

Pituitary Body in Mongolism.—Benda examined microscopically the pituitary bodies of thirteen supposedly mongoloid patients and of one case of premature birth. The definite alterations peculiar to mongolism consisted of an increase of eosinophilic cells and a deficiency of basophilic and chief cells. In analyzing these alterations the author believes that, because the size of the pituitary is not increased and no signs of eosinophilic hyperactivity are found, the absence or deficiency of basophilic cells appears to be the most important observation. There are many indications that mongolism is the result of a morphokinetic failure and is due to an endocrine disturbance. The key to the general disorder seems to be a particular pituitary deficiency, which may be due to a pituitary deficiency of the mother during pregnancy. The advanced maternal age, frequently observed in cases of mongolism, and other factors indicate that the maternal organism is not apt to adjust itself to a new pregnancy.

Hypothalamic Nuclei in Heat Stroke.—The nuclei of the hypothalamus in thirteen patients who died of heat stroke were studied by Morgan and Vonderahe and compared with the nuclei of the hypothalamus in five control brains from patients who died of a variety of causes (malignant hypertension, gunshot wound in the back, skull fracture, pulmonary tuberculosis and mercury bichloride poisoning). Eleven of the thirteen patients with heat stroke were men. Twelve of the thirteen were 50 years of age or older. In all twelve cases in which complete necropsy was performed, heat stroke was associated with some pathologic process tending to produce degenerative changes in the central nervous system. In nine it was associated with generalized vascular sclerosis, in two with syphilis and in one with chronic alcoholism. The nucleus paraventricularis in cases of heat stroke presented an average cell loss of 27 per cent; of the cells that remained, an average of 77 per cent were normal. The large cells of this nucleus were principally affected as compared with diabetes mellitus, in which the small and medium sized cells were principally affected. The nucleus tuberis lateralis presented an average cell loss of 40 per cent; of the cells that remained, an average of 47 per cent were normal. In the control cases, pathologic alterations frequently occurred in the cells of this nucleus, the average of normal cells being 65 per cent. The nucleus tuberomammillaris presented no decisive alteration in cell counts. There was, however, general and constant pathologic change, with an average of only 27 per cent of cells remaining normal. The basal optic ganglions (nucleus supra-opticus) and the cells of the substantia grisea did not present sufficiently significant constant cell loss. Chromatolysis, while variable, was of a sufficient degree so that the heat-regulating functions of these structures were considered. The most likely interpretation that the authors place on their observations is that the lateral nuclei of the tuber and a portion of the paraventricular nuclei are primarily concerned

with elimination of heat. The nucleus tuberomamillaris, which is acutely affected in both experimental fever and heat stroke, is probably concerned with heat production (metabolism). If, then, in cases of heat stroke the mechanisms for heat elimination are weakened it is possible that these mechanisms break down when subjected to an extremely high environmental temperature. These mechanisms having broken down, the normal balance between heat production and heat elimination is destroyed. This may remove a part of the normal checks or inhibitions from the mechanisms for heat production so that the total metabolism is accelerated rather than inhibited.

Colloidal Aluminum Hydroxide for Peptic Ulcer.—

Whitcomb compares the results of treating fifty cases of peptic ulcer with colloidal hydroxide, forty-five with the Sippy regimen and nine by means of various other medical methods. When compared with the Sippy regimen the use of colloidal aluminum hydroxide reduced the length of hospitalization for the series by 560 hospital days. It promoted a more rapid and definite healing process as demonstrated roentgenologically, symptomatic relief and lack of recurrences. The latter feature may be due in a large part to the simplicity of this method of treatment, which is an advantage over the more detailed Sippy regimen and therefore more likely to be followed after the patient has been discharged. Other advantages are the increased activity permitted during treatment and the wider latitude in diet, which permits the free use of essential foods. Of the patients treated with colloidal aluminum hydroxide healing was demonstrated at an earlier date in those receiving the treatment by the constant drip method. This method appeared more effective in cases in which there was a high acid curve. The method was preferred by the refractory and those patients whose condition required more drastic methods—as in one case showing by x-ray examination a chronically indurated postpyloric ulcer with a marked obstruction and twenty-four hour residue. In twenty-one of the admissions reviewed, symptoms were not relieved by Sippy treatment. In nine, aluminum hydroxide was subsequently given with prompt relief of symptoms. In another case of Sippy failure, aluminum hydroxide therapy, strictly followed for one week, also failed to relieve severe pyrosis following several hemorrhages. This was the only case of the series in which a surgical operation following failure to control the symptoms by colloidal aluminum hydroxide also failed to control the symptoms. Seven of the cases that were treated effectively by aluminum hydroxide were recurrences following surgery. There were no recurrences in the cases treated by aluminum hydroxide as compared to 13.5 per cent of the Sippy cases. The failure to control symptoms during treatment was four times as great among those on the Sippy regimen.

Prevention of Purulent Otitis Media.—Clinical observation over a period of five years has led Bakwin and Jacobziner to believe that incising an inflamed drum often leads to a purulent discharge in an ear in which, if there were no operative intervention, the infection would subside spontaneously. Furthermore, the results over a period of five years strongly indicate that frequent examinations of the ear, by traumatizing the drum and the canal and by exposing the nasopharynx of the infant to the expired air of the examiner, favor the development of purulent otitis media. In many pediatric hospitals otitis media is treated casually and its management is left to the house officers without adequate supervision by the visiting staff. This attitude is fraught with danger, as it exposes children already ill to the danger and inconvenience of unnecessary paracenteses and purulent otitic discharges. Though disease of the mastoid is uncommon in infants, it does occur and is to be avoided if possible. By careful supervision, strict adherence to a standardized set of indications for myringotomy and the avoidance of too frequent examinations, the incidence of purulent otitis media may be reduced and the danger of disease of the mastoid lessened. The authors state that the results of their study lend no support to the view that delay in incising an ear drum is harmful to the child. When doubt exists, they believe that it is preferable to wait. In acute intestinal intoxication, when a specific relationship to acute purulent otitis media has been hypothesized, the incidence of aural discharge has been reduced to one third during the five years under discussion, with a fall rather than a rise in case fatality from this serious disease.

Bronchography in Children.—As a substitute method for local anesthesia employed in bronchography in conscious children Lester and Rovenstine describe a technic of inhalation anesthesia with nitrous oxide-oxygen, after basal narcosis with tribromethanol in ethylene hydrate and the application of a 3 per cent solution of metycaine to the mucous membranes. The method permits the accurate introduction of the contrast medium by way of an endotracheal tube and the removal of most of it after the bronchographic examination is completed. Results after more than one year's trial indicate that the method is relatively safe, pleasant for the patients and time saving, and also that the results have been more satisfactory than with any other technic used.

Pectin-Agar Diets for Bacillary Dysentery.—Winters and his colleagues used a pectin-agar preparation of maltose and dextrin in the treatment of fifty-two cases of bacillary dysentery and twenty-seven cases of infectious gastro-enteritis, probably dysentery, in infants and children. Soft stools were produced within an average of thirty-four hours and a gradual and steady improvement took place in 73.4 per cent of the children. The daily intake averaged from 33 to 52.4 calories per pound, and average weight gains were observed in every group. The mode of action of this therapy is probably both physicochemical and mechanical, with the uronic acids playing an important part. The diet, besides having a definite therapeutic action, is high in calories, well balanced and easily assimilated, and it maintains nutrition while the body has a chance to develop the necessary immunity. The authors find that the pectin-agar diet definitely produces formed stools more quickly with fewer recurrences than other accepted methods, including the apple diet.

Sulfanilamide and Specific Serum for Pneumococcal Meningitis.—Gray and Adams report a bacteriologically proved case of pneumococcal meningitis with recovery. The condition was complicated by granulocytopenia and otitis media

and had the unusual residual of complete involvement of both bilateral eighth cranial nerves. Both sulfanilamide and specific serum were used and therefore the efficacy of either one alone could not be determined. Spinal drainages were done daily just preceding each intraspinal injection of serum and for four days after serum was discontinued. The drainages were probably a helpful therapeutic adjunct but no more than that. Eradicating a focus of pneumococcal infection, had there been one present, would have been of more value. The total amount of serum given was about twice that which is now considered sufficient. The granulocytopenia was due to toxicity or idiosyncrasy to sulfanilamide, since the patient had nausea and vomiting when the blood level of the drug was only 5.3 mg. per hundred cubic centimeters and had a secondary rise in temperature four days before the leukocyte changes were noticed. Although the patient was catheterized twenty-five times the urine was regularly negative, probably because of the antiseptic action of the sulfanilamide.

Dihydratichysterol for Tetany.—Hurxthal and Claiborne used dihydratichysterol in six cases of postoperative tetany. The status of these patients was well known, as they had had tetany for two years or more. Four could be symptomatically controlled with calcium by mouth. Only three patients are still taking the preparation; the others had to discontinue its use because of its high cost. In the milder cases, calcium by mouth was stopped for from two to four weeks; dihydratichysterol was then begun in doses ranging from 12 to 20 cc. during the first four or five days, but thereafter it was reduced to 1 cc. daily or 1 cc. every other day. In the severe cases calcium was stopped and the preparation was begun immediately in larger doses, but shortly thereafter from 1 to 3 cc. daily was prescribed. Later, available calcium in the form of calcium lactate, chloride or gluconate was prescribed orally. No toxic symptoms were observed except in cases in which the blood calcium rose above normal. Two patients had a hypercalcemia. In one of these, headache developed and the patient had an extreme aversion to taking the calcium; nausea was also present. The other patient complained of loss of appetite, nausea, headache and lassitude. Both patients soon lost their symptoms when the preparation was discontinued; one even went through pregnancy without additional medication. Following delivery the dose was increased, during which time hypercalcemia developed. The daily requirement of the preparation apparently depends on the extent of the deficiency. Doses of from 2 to 5 cc. weekly are sufficient to control the milder moderate cases. When the blood calcium has reached a normal level, an arbitrary dose of from 0.5 to 2 cc. is prescribed until the daily or weekly requirement is worked out. It is advisable to give calcium by mouth whenever it can be tolerated, as it reduces the amount of the preparation required and in turn provides soluble calcium. In spite of arguments in favor of other calcium preparations, calcium lactate in the authors' experience is most tolerable.

Roentgen Treatment of Carbuncles.—O'Brien points out that the mortality among 130 hospitalized patients with severe carbuncle receiving roentgen therapy alone or in conjunction with surgery was 3 per cent. There were no deaths among fifty-seven patients with facial carbuncle treated either alone

or chiefly by radiation. There was no evidence that carbuncle in the diabetic patient was a contraindication to roentgen therapy. The sixty patients who were treated early only by x-rays had a shorter convalescence than did the others.

Testosterone Propionate for Gynecologic Disorders.

—In the treatment of twenty-two patients with various functional gynecologic disorders Greenhill and Freed used testosterone propionate. The patients were placed in three groups, those receiving injections during the first two weeks of the menstrual period, the second two weeks and the entire month. The doses of testosterone propionate ranged from 25 to 50 mg. every other day except on a few occasions when even more was administered. Injections of from 25 to 50 mg. every other day during the first two weeks relieved only two of the eight patients, one with menorrhagia and one with dysmenorrhea and menorrhagia. The improvement was judged to be about 50 per cent. One patient with dysmenorrhea and menorrhagia received 850 mg. during this period without relief. The menses in this case were, however, delayed for about twenty days. Injections of from 25 to 50 mg. to four patients with dysmenorrhea and two with premenstrual tension during the second two weeks of the period produced complete relief in one case of dysmenorrhea, moderate relief in two and slight relief in one. The two patients with premenstrual tension were not improved. The menses of patients in this group were not delayed significantly. The third group made up the most distressing cases: four patients with severe functional menorrhagia, two with excessive bleeding due to fibroids, one of dysmenorrhea and one with premenstrual migraine. The amount injected in all except the case of premenstrual migraine was 500 mg. or more during the month; the patient with migraine received 250 mg. during this time. The results in this group were gratifying in that one patient with severe functional dysmenorrhea improved considerably and one patient with intractable menorrhagia and dysmenorrhea who received 800 mg. in one month had normal periods for the first time in many years despite extensive endocrine therapy of all sorts. One patient with menorrhagia failed to improve and required irradiation of the ovaries. The two patients with bleeding due to fibroids responded very well. During the period of injections the fibroids regressed but within two months after the injections were stopped they returned to normal size, although the excessive bleeding did not reappear. Two patients with functional menorrhagia had an associated endometrial hyperplasia of the "Swiss cheese" type. The endometrium in both cases underwent atrophy and the bleeding ceased for at least two months. The patient with migraine was unimproved. Menses were suppressed in all patients in this group who responded well to this therapy.

Surgery of Adrenal Cortex. L. R. Broster.—p. 925.

Pituitary Adenomas.—Henderson reports the surgical results of 338 histologically verified pituitary tumors observed at the Brigham Hospital during a period of twenty years. The report deals principally with surgical mortality statistics, the early results of operation and a follow-up study of the patients, the last of whom was operated on July 23, 1932. Only three of the 338 patients have not been heard from since their discharge from the hospital. There were 260 chromophobe adenomas (including thirty-two mixed adenomas), sixty-seven acidophil adenomas and eleven adenocarcinomas. No example of a basophil adenoma has been identified. The incidence of pituitary adenomas in Cushing's series of 2,023 verified intracranial tumors is 17.8 per cent. Chromophobe adenomas produce only local compression effects, whereas acidophil adenomas evoke general constitutional disturbances and often local effects in addition. The adenocarcinomas are apt to infiltrate surrounding structures. The various extrasellar extensions are surgically important. The operative procedures are referred to briefly, especially the more radical excavation of the intrasellar tumor and the immediate liberation of the chiasma by the transfrontal operation; also the importance of ventriculography in selected cases with intracranial extensions and the use of lateral flaps for the removal of extensions which are shown by ventriculography to be accessible. The late results, analyzed on the basis of the duration of improvement after operation, indicate great variability in the rate of growth and behavior of the chromophobe adenomas. After a successful transphenoidal operation without irradiation some patients had no further trouble for as long as twenty years. On the other hand, a rapid recurrence within two or three years may take place even after a far more radical transfrontal operation plus roentgen treatment. While many patients maintained this improved status for from ten to twenty years, 95 per cent of those who had a recurrence showed indications of it within five years after operation. The clinical course of acidophil adenomas differs from that of the chromophobe adenomas. The two types of symptoms—local pressure (visual) effects and systemic effects—frequently show spontaneous remissions and exacerbations and often respond differently to treatment. Operation usually produces marked improvement in vision but may have no effect on the severe headaches, especially in cases in which there is a small tumor. The systemic disturbances are

ultimately apt to be the most serious because of the deleterious effects of the hormone secretion on the cardiovascular system and on sugar metabolism. The operative mortality is slightly higher than for the chromophobe adenomas, but the late surgical results appear to be better. The acidophil tumors are more amenable to roentgen therapy. The adenocarcinomas have not yet been subjected to sufficiently thorough pathologic study. Clinically, some of them behave like chromophobe adenomas; others, however, are hopelessly malignant, infiltrate the base of the skull and produce multiple cranial nerve palsies.

Progesterone and the Nasal Mucosa.—Willson-Pepper and Royle report a case in which menorrhagia had existed for two years and spasmodic rhinorrhea of considerable severity for eighteen months. The nasal passages had been examined thoroughly and roentgenograms of the nasal sinuses were made but no evidence of infection had been found. The nasal septum was removed, as it was partially blocking the airway, but this failed to give relief. After the first injection of progesterone the nasal discharge and congestion immediately subsided and has not reappeared for several weeks. That some relationship may exist between the nasal mucosa and sexual activity has been observed for centuries. The effect of progesterone, the authors believe, in controlling severe rhinorrhea merits further investigation and if carried out in a sufficient number of suitable cases might yield valuable results.

Control of Staphylococci in Operating Room.—Devenish and Miles encountered a high incidence of suppuration due to Staphylococcus aureus in "clean" operative wounds which was due to the leakage of Staphylococcus aureus through glove punctures from the skin of one surgeon who proved to be a skin carrier. The Staphylococcus aureus present in the air of the operating room and on the skin of the patients operated on apparently played no part in the incidence of suppuration. Nasal carriers of Staphylococcus aureus among the operating staff do not constitute a danger, provided masks are made imperme-

able to direct droplet discharge from the nose and mouth. All the strains of Staphylococcus aureus tested on press plates fermented mannitol and produced a coagulase for human plasma. Skin carriers, negative by the ordinary swabbing tests, may sometimes be detected by cultivating the sweat from the inside of rubber gloves at the end of an operation. This method has the advantage of excluding positive results due to temporary superficial contamination of the skin. The frequency of glove puncture during operation was found to be as high as 24 per cent; this was reduced to 14 per cent by precautions to avoid puncture.

Specific Gravity of Blood in Pneumonia.—Elphinstone and Ward determined daily the specific gravity of the blood in fifty-four consecutive cases of acute lobar pneumonia (forty-two men and twelve women). Leake, Kohl and Stebbins report an average figure of 1.0568. The specific gravity of the blood is said to be three or four degrees lower in women than in men. It is more constant in normal or convalescent subjects from day to day than in patients with pneumonia. Since fewer estimations of the specific gravity of the blood were possible in some cases than in others, the highest figure recorded for each patient is regarded as the most satisfactory common denominator. Consideration of the highest figure for each patient in relation to the severity of the illness shows that the specific gravity of the blood was above 1.059 in only four of the thirty-two mild and average cases, whereas figures above 1.059 were recorded in fifteen of the twenty-two severe and fatal cases. Among the fatal cases the highest recorded specific gravity of the blood was below 1.06 almost as often as not. Of the fourteen patients whose highest figure was from 1.06 to 1.062 only four died, but nine were seriously ill. Of the six patients with figures of 1.063 or more five died, a mortality of over 80 per cent compared with 30 per cent for the whole series, and less than 25 per cent for the patients with a specific gravity of the blood of below 1.063. Thus the severity of the illness was apparently related to the specific gravity of the blood.

Thyrotrophic Hormone.—Harrison gave thyrotrophic hormone to five patients exhibiting different types of thyroid insufficiency. The patients were all maintained at rest in bed for some time before and during the period of study. The basal metabolism estimations were performed by the Douglas bag technic. Two patients with secondary thyroid insufficiency showed an elevation of the basal metabolic rate following the administration of the hormone, two with primary hypothyroidism responded slightly and a patient whose thyroid had been removed gave no response at all. In four of the five patients the administration of hormone was followed by a significant fall in blood cholesterol. The fall in the blood cholesterol level might have been effected by the stimulation of a residuum of thyroid tissue which was not sufficiently large to elevate the basal metabolic rate. In other words, the cholesterol level of the blood might have responded more sensitively than the metabolic rate to a slight increase of thyroid activity. Those conditions which should provide the only fertile field for prolonged therapy with thyrotrophic hormone are those in which there is secondary hypothyroidism due to a primary pituitary insufficiency. Some such patients respond to thyroid extract less rapidly than do patients suffering from a similar degree of primary thyroid insufficiency. A test dose of thyrotrophic hormone will help to distinguish between primary thyroid insufficiency and hypothyroidism secondary to pituitary insufficiency.

Varices in Course of Pregnancy.—Vignes studied 131 pregnant women, of whom seventy-six were primiparas and fifty-five were multiparas; forty-one of the primiparas and twenty-three of the multiparas were without varices; nine of the primiparas and four of the multiparas had had varices before gestation. Of the fifty-four women who had gravidic varices, twenty-six were primiparas and twenty-eight multiparas. Pregnancy is the time at which varices are most likely to appear. In this connection the author cites Stübel, who reported that of fifty-four women with varices forty-eight attributed the onset of the disorder to a pregnancy. The time of appearance of gravidic varices differs. In some women their appearance is a veritable diagnostic sign of pregnancy in that they appear shortly after the first suppressed menstruation. Of thirty-one women of the author's material in whom the time of appearance of the varices was known, twelve developed the varices during the first three months of pregnancy, fifteen during the second three months period and four during the seventh month. He concludes from this that in the majority of cases the varices appear before the volume of the uterus can hinder the course of blood in the legs. The varices are most frequently located in the legs. However, other localizations are possible: they have been observed on the arms but especially on the vulva, vagina, uterus, round ligaments, suprapubic region and breasts. The varices of the round ligament may give rise to an incorrect diagnosis in that they are readily mistaken for inguinal hernia. The varices appearing in the course of a pregnancy generally undergo involution which may even lead to complete disappearance. This possibility of their amelioration contraindicates treatments disproportionate with their benign character. Discussing the causes of gravidic varices, the author shows that the imperfection of the mechanical explanations leads to emphasis on the role assumed by insufficiency of the venous tonus, which in turn may be due to various factors (constitutional, hereditary endocrine and so on). In the last part of his discussion he calls attention to the fact that during as well as outside of pregnancy varices may lead to diverse complications such as rupture, eczema, ulcer, neuritis, phlebitis and periphlebitis. Rupture is noteworthy when it occurs in the region of the vagina or of the uterine cervix, since the resulting hemorrhages may be taken for a symptom of placenta praevia. If varices are ruptured in the region of the parametrium they may give rise to large hematomas, which in turn may cause dystocia. The author directs attention to varicose phlebitis and periphlebitis, although he admits that they are not frequent. Periphlebitis may lead to obliteration of the vein and terminate in suppuration; varicose phlebitis may give rise to fatal pulmonary embolism.

Osteopathies Caused by Bismuth.—Racouchot demonstrates that the abuse of the therapeutic application of metals, especially bismuth, gives rise to osteopathies. They are, in general, of the osteoporotic type. The author cites several

case histories and shows that the osseous resorption of bismuth is of the same type as that which is encountered in cases of lead poisoning. In this connection he cites observations and experiments made by Askanazy and Rutishauser. These investigators observed osseous changes in lead poisoning and were able to produce osteopathies experimentally, demonstrating that metals are of primary importance among the exogenic causes of osteopathy. The author suggests the term osteopathy because in the absence of anatomic verification it is impossible to determine the exact nature of the osseous process. He says that the relation between the metal and the osseous disorder is not surprising if attention is given to certain conditions that are observed in the course of bismuth therapy. He cites the osteo-articular pains; the phosphaturia, which is indicative of considerable decalcification; the frequency of gluteal calcifications at the point of injection of bismuth, and finally the buccal elimination of bismuth. Like lead and mercury, bismuth is eliminated with predilection at the gums. The author says that although the osteopathies caused by bismuth are comparatively rare, there is danger that they may increase if bismuth is administered over long periods.

Cerebrospinal Fluid in Chronic Polyarthrititis.—Graber-Duvernay and Gerbay studied the cerebrospinal fluid in chronic polyarthrititis with regard to the formulation of the prognosis, the selection of the treatment, particularly of chemotherapy, in the differentiation of the chronic forms and in similar problems. Their clinical material was comparatively limited; that is, they made their investigations on eighteen patients with chronic polyarthrititis. Although they were unable to obtain definite answers to all the questions, they found that there is usually an augmentation of the albumin content of the cerebrospinal fluid in chronic polyarthrititis; however, the sugar content does not undergo variations and the cell count likewise reveals normal values. The authors raise the question whether this dissociation between the albumin content and the cell count is the manifestation of a meningomedullary compression or at least of a more or less discrete arachnoid-radicular one. They point out that ordinarily the presence of hyperalbuminosis indicates a lesion of the nervous system and they cite observations which indicate a nervous involvement in chronic polyarthrititis. They found that the hyperalbuminosis is an extremely early sign and is of prognostic and diagnostic significance. A lumbar puncture is indicated when doubts exist about the evolutive character of a polyarthrititis; if it reveals the presence of a hyperalbuminosis, the prognosis must be made with reservation and active treatment, such as gold therapy, is indicated. The examination of the cerebrospinal fluid seems to be superior to that of the sedimentation speed of the erythrocytes in determining the advisability of the resumption of chemotherapy. In cases of chronic polyarthrititis with moderately accelerated sedimentation speed a new series of treatments with gold salts is unnecessary if the albumin content of the cerebrospinal fluid is normal. The exploration of the subarachnoid space has an important part also in determining the advisability of articular redressements, because the clinical aspects frequently do not give sufficient information in this respect. The authors show that it is inadvisable to resort to articular redressement whenever there exists a hyperalbuminosis of the cerebrospinal fluid; that is, whenever the albumin content exceeds 0.5 Gm.

- Anterior Perinephric Phlegmon. Vergoz and Lenck.—p. 369.
- *Treatment of Prostatic Retention of Urine by Endo-Urethral Resection of Prostate. R. Denis.—p. 395.
- Endo-Urethral Treatment of Retention of Urine Caused by Cancer of Prostate. R. Denis and P. Dufour.—p. 410.

Endo-Urethral Resection of Prostate.—Denis presents his report on endo-urethral resections for prostatic hypertrophy and says that since 1934 he has treated all operable prostatic retentions by the urethral route, no matter what was the volume of the prostate or the age of the patient; he thought that by thus extending the indications for endo-urethral resection to the limit it would be possible to obtain an insight into the real value of the method and then the indications could be limited on the basis of the disappointments. The author operated on

105 patients "with closed bladder." For 103 of these patients the results were favorable, one patient died and for another one the operation was a failure, it having resulted in a definite cystotomy. The operation was performed also on thirty-five patients "with open bladder." Among this group there were two deaths and two failures; in the other thirty-one patients normal micturition was restored. The author analyzes his observations on the two groups of cases and says that endo-urethral resection is easy in the small prostatic hypertrophies but rather difficult in hypertrophies of considerable volume. He thinks that this explains why the majority of surgeons limit this operation to the small prostates. However, it is important to know that the chief difficulty is encountered at the beginning of the resection, that is, after the beak of the apparatus has hardly passed the obstacle; it is not mobile, the field is extremely narrow and the introduction of the apparatus has already caused so much bleeding that the surgeon is much inconvenienced by the hemorrhage. At this point the resection should not be given up, because after several rapid cuts of the knife the apparatus is mobilized, hemostasis is made and the field is enlarged; after several more cuts the hemorrhage is arrested with great care and there is sufficient space so that the volume of the organ is no longer a hindrance and the surgeon is master of the situation. The resection is then carried out methodically, each lobe in its turn. The difficulty now is in determining the moment when it is necessary to stop because the resection is sufficient. The author discusses the procedure on the median and lateral lobes. In the conclusion he stresses that he is glad that he introduced endo-urethral resection into his current urologic practice. He does not regret that he employed the method even on large prostates. The majority of patients have clear urine, no difficulty of micturition and no residue. The author observed no relapses and the patients were satisfied.

*Benzene Myelotoxicosis: Clinical and Hematologic Study of Ten Cases of Occupational Intoxication by Benzene Compounds. M. Lamy, P. Kissel and L. Pierquin.—p. 467.

Anemia of Acute Malaria. J. Lebon and A. Manceaux.—p. 489.

Grave Acute Hemolytic Anemia with Leukemoid Aspects, Following an Angina Treated by Various Chemical Agents: Pathogenic Considerations. N. Gingold and G. Comsa.—p. 517.

Benzene Myelotoxicosis.—Lamy and his associates studied most of their patients over periods lasting several months, the bone marrow was studied in all and in some of them repeatedly. Moreover, in four fatal cases they were able to compare the myelograms with the histologic pictures of the bone marrow. The studies were made on ten workers of a shoe factory who had been exposed to chronic intoxication by benzene compounds. The intoxications were severe, five of them resulting in death. The authors describe the histories of the ten patients and also give a tabular survey which lists the clinical signs, the hematologic and medullary aspects, the final outcome and the post-mortem observations on the bone marrow in the fatal cases. Further they discuss the variable evolution of benzene poisoning, the changes on organs other than the bone marrow, particularly the liver, the prognosis and the therapy. Summarizing their observations they state that in the majority of cases the benzene intoxication produces a complex hematologic syndrome which is characterized by the signs of anemia, purpura and granulocytopenia. In contradistinction to this uniform hematologic picture, the myelographic aspects are multiform: in the mild cases, there exists a simple erythroblastic reaction; in the grave cases there exists total medullary aplasia, perhaps associated with a hyperplasia of the cells of the reticulo-endothelial system. Reservation is necessary in estimating the prognosis of the benzene hemopathies, for even after the patients have been removed from intoxication they are still subject to relapses. Repeated examinations of the blood and of the bone marrow are indispensable for the establishment of the prognosis. The therapy of grave benzene hemopathies is extremely deceptive. Only repeated blood transfusions have any efficacy. The authors think that the only efficient prevention of occupational intoxication with benzene compounds consists in legal or administrative regulations prohibiting the use of benzene compounds in certain industries.

Experimental Contribution to Treatment of Hypertension. F. Rothschild and C. Meili.—p. 255.

Contribution to Study of Surface Tension of Blood Serum. A. Gigon and M. Noverraz.—p. 264.

Late Results of Surgical Sterilization in Women.—In order to determine how women feel about sterilization in their later years, Wenner sent questionnaires to the women who had undergone sterilization at the clinic in Basel during the years between 1920 and 1933. A table which lists the indications for the 1,069 sterilizations shows that in 174 cases social factors were the only indications and that in 126 additional cases the social factors motivated the sterilizing operation, but there existed some other factor (medical, gynecologic or eugenic) which further supported the advisability of the sterilization. The author reproduces the questionnaire that was submitted to 904 of the 1,069 women and was answered by 742 of them. Of this number thirty-six, 4.8 per cent, were not satisfied and regretted the sterilization. Seven of these had physical complaints (pains, ovarian insufficiency and so on); in all others the complaints were of a psychic nature, such as unrequited maternal instinct, feeling of inferiority, mental depression, religious scruples and frigidity. From the fact that 95.2 per cent of the women were satisfied with the results of the sterilization, the author concludes that there is no need to deviate from the course that has been followed so far.

*Early Diagnosis of Carcinoma of the Cervix Uteri. H. Wespi and D. Brasch.—p. 4.

Estrogen Excretions in Urine of Pregnant Women. Elisabeth Dingemans, E. Laqueur and O. Mühlbock.—p. 37.

Syphilis and Carcinomas of the Cervix Uteri. M. Sorba.—p. 49.

Diagnosis of Carcinoma of Cervix.—Wespi and Brasch report the clinical observations in nine cases of primary carcinoma of the cervix. These observations extended over more than two years, the authors employing the colposcope, the iodine test and microscopic analyses on the basis of Hinselmann's classification. The age of the patients ranged between 32 and 52 years, with an average of 41.5. The authors' purpose was to arrive at a comparative evaluation of the microscopic and colposcopic pictures and a rapid survey of the extension and nature of histologic modifications. Serial sections were performed on eight patients. The nine patients were divided into three groups. In group 1 (five patients) carcinoma was discovered only through the colposcope. In group 2 (two patients) colposcopy confirmed macroscopic suspicions. In group 3 (two patients) one case of carcinoma was detected without the colposcope; in the other case the malady was too deep seated to admit of colposcopic determination. In their epicritical comments the authors point out several microscopic peculiarities. Besides areas with manifest inward penetration and pronounced atypias of a carcinomatous nature there were extensive portions with marked atypical epithelium but without any indication of penetrating growth, an indication of cancer of multicellular origin, the connection established by an atypical epithelium, called "matrix" by Hinselmann. In three patients abnormal epithelium was found besides the atypical. Nearly all of the seven patients successfully examined with the colposcope revealed various modifications such as leukoplakia, to which according to the authors no undue significance should be attached. Coarse, heavy proliferations and red surfaces that bled easily on being touched along with other "matrix" areas invited suspicion of the presence of a carcinoma. Whenever the atypical epithelium extended beyond the colposcopically suspected areas, application of the iodine test adjudicated the doubt. The authors state that they employed the Schiller test with greater frequency to distinguish patients with atypical and hence carcinomatous epithelium from those with abnormal epithelium. None of their patients showed the characteristic symptoms of early carcinoma, such as bleeding on contact and

bloody discharges. They therefore stress the significance of the period of latency and emphasize the value of precautionary examinations, if the colposcope and iodine test are resorted to from the beginning. In three of their cases the iodine test paved the way for subsequent colposcopy. In one case colposcopy had to be repeated a second time for the sake of diagnostic validity. The authors also note that surgical intervention frequently was attended by difficulties in technic because of periuterine inflammation. In all cases but one initial amputation had to be followed by complete excision, the latter resulting in one death.

*Anemic Syndromes After Operations on Stomach. A. Chiatellino.—p. 125.

Consequences of Denervation of Thyroids. A. Chiatellino.—p. 146.

Anemic Syndromes After Gastric Operations.—Chiatellino examined the blood of 472 patients who had duodenal or peptic ulcer and who had undergone an operation on the stomach during the last few years. The operations consisted of resection (Reichel-Polya) in 224 cases, gastro-enterostomy in 197 and hemipylorotomy in fifty-one. The 200 men operated on (no matter what the type of operation) had a normal crisis of the blood. In eighteen of the thirty-one women who had gastric resection and in one of the twenty-six who had gastro-enterostomy, subacute hyperchromic anemia occurred which improved after administration of iron and recurred some time after its discontinuance. None of the eleven women who had hemipylorotomy developed anemia. Anemia did not develop in any of the cases sooner than two years after operation. The majority of the women who developed anemia were nearing the menopause. The author believes that operations on the stomach, especially resection, may induce a functional disorder for the assimilation of iron.

*Surgical Treatment of Lymphogranulomatous Stenosing Rectitis. E. Vasconcelos.—p. 19.

Testicular Ectopia: Torek's Operation. N. M. Barros Filho.—p. 47.

Lymphogranulomatous Stenosing Rectitis.—Vasconcelos describes a technic for surgical treatment of lymphogranulomatous stenosing rectitis in women. In all cases the length of the sigmoidal segment and the evolutionary phase of the disease are determined before the operation by x-ray examination and rectoscopy, respectively. When the sigmoid is long and there are no complications, the treatment consists in lowering the rectosigmoid segment toward the perineum, removing the involved portion of the rectum and suturing the sigmoid to the sphincter and perineum. If the segment is short and there are no complications and also when fistulas and sphincteral and genital lesions are already developed, the operation consists in making a permanent sigmoid anus and removing the involved segment including the rectal sphincter. The operation is made in two stages (abdominal and vaginoperineal). In all cases spinal anesthesia is used and salpingectomy is also performed. The steps of the abdominal stage include a median abdominal incision, exposure of the surgical field, sectioning of the pelvic peritoneum at the mesosigmoid, ligation of the local vessels, separation of the rectosigmoid segment from the neighboring structures down to the point at which the median hemorrhoidal vessels appear, pushing of the isolated colirectal segment toward the perineum, suturing of the cut pelvic peritoneum to the sigmoid after the latter is already lowered, and closure of the peritoneum by planes without the placing of any drain. The vaginoperineal steps include reconstruction of the ruptures of the perineum and of the rectal sphincter which were caused by the previous vaginorectotomy, further separation of the rectosigmoidal segment, ligation of the local vessels and removal of the involved segment through the perineum. The next technical details are rectoperineal reconstruction, myorrhaphy of the elevator muscles with sutures to the wall of the lowered colon, myorrhaphy of the sphincter, suture of the vaginal mucosa and of the anterior perineum and also suturing of the colon to the skin of the perineum. The draining or placing of a sound at the lumen of the intestine is not necessary, but a sound is temporarily left in the bladder. A

permanent sigmoid anus is performed either with or without a previous vaginorectotomy by the technic described with the following modifications: The rectocolic segment is not pushed down to the perineum during the abdominal stage, but after it is isolated from the neighboring structures the sigmoid is cut. The proximal sigmoid segment is implanted to the abdominal wall at the iliac fossa for making a sigmoid anus, whereas the distal sigmoid-rectal segment is removed in a block together with the sphincter, the involved soft parts and the involved parts of the perineum, by the perineal route. Reconstruction of the elevator muscles, which are preserved, and suturing of the vagina and of the perineum are carried on by the ordinary technic.

*Tendency to Normalization of Electrocardiogram of Patients with Angina Pectoris Undergoing Irradiation of Adrenals. W. Raab and E. Schönbrunner.—p. 362.

Electrocardiogram Following Irradiation of Adrenals.

—According to Raab and Schönbrunner it has been suggested that in the so-called simple angina pectoris which appears during exertion, excitement, influence of cold and so on the excessive elimination of epinephrine from the adrenals is concerned in the causation. Since it has been demonstrated that roentgen irradiation of the adrenals restricts the production of epinephrine, it was decided to employ this treatment in angina pectoris. The authors describe electrocardiographic studies on thirty-eight patients with simple angina pectoris who were treated with roentgen irradiation of the adrenals. They found that twenty-eight of them were either improved or entirely free from symptoms after one or several series of roentgen irradiations. Sixteen of these twenty-eight improved patients had had a pathologic electrocardiogram before the treatment, that is, in thirteen the electrocardiogram had been of the type that is characteristic of diffuse or circumscribed hypoxemia of the myocardium and in three it had been of the type that is observed in disturbances of the intraventricular conduction. In ten of the thirteen patients who had had an electrocardiogram characteristic of hypoxemia the electrocardiogram, in harmony with the subjective condition, had become more or less completely normalized after the roentgen treatment. In the three other subjectively improved cases with the electrocardiographic aspects of hypoxemia and in three with those of irreversible intraventricular conduction disturbances there were no objective changes. One of the first three died four months later as the result of coronary occlusion. In seven patients with the electrocardiographic aspects of hypoxemia, in whom there was no subjective improvement following roentgen therapy, the roentgenogram likewise showed no tendency toward normalization. There were no relations between the height of the blood pressure and the reaction of the subjective condition and of the electrocardiogram. The frequent normalization of the electrocardiogram of patients with angina pectoris who were subjectively improved following roentgen irradiation of the adrenals objectively proves the efficacy of this treatment.

*Transfusion of Blood Conserved According to New Method. F. Corelli.—p. 716.

Attempt to Treat Case of Nontropical Sprue with Nicotinic Acid. H. Fuchs and A. Wisselink.—p. 722.

Transfusion of Conserved Blood.—Corelli says that in the course of studies on allergic diseases he observed that if blood is brought together with various thiosulfate solutions it stays fluid and for many days, up to one month, it remains in

a good state of conservation. Recalling, moreover, that thiosulfate is not toxic and that it has a desensitizing effect, he decided to use it for the conservation of blood, the more so since blood transfusions may become complicated by allergic phenomena. One of the advantages of the use of thiosulfate is that a small quantity of solution is sufficient to keep the blood in a fluid state; other solutions that are used for this purpose, for instance the one employed by the Russians, requires equal amounts of blood and solution so that, if 400 cc. of blood is to be given, 800 cc. of fluid must be injected, which may not be always desirable. The author found that 7.5 cc. of solution of thiosulfate is sufficient to preserve 100 cc. of blood for more than one month. If blood is to be conserved only for a few hours, 7.5 cc. of thiosulfate solution is enough for from 125 to 150 cc. of blood. In the specimens of blood that were preserved with thiosulfate it was observed that, if the blood had been withdrawn from a fasting person, the supernatant fluid remained entirely clear. A slight hemolysis began at various times in some blood specimens between the tenth and fifteenth days, in others earlier or later. After numerous animal experiments had demonstrated that blood preserved by means of solution of thiosulfate is well tolerated, the author used this type of blood on human subjects. He used it in 450 transfusions in various internal, surgical and obstetric disorders. The quantities varied between 100 and 500 cc. and in some cases the transfusions were repeated. In the majority of cases the blood had been preserved for from one to two weeks, but some transfusions were made with blood that had been preserved for from sixty to sixty-two days. The technics of withdrawal and conservation as well as of transfusion are simple. If the conserved blood is to be used for transfusion it is merely heated in the water bath until it reaches a temperature of from 95 to 100.4 F. In order to insure homogenization the blood should be moved with rhythmic rotating movements while it is warming up. Transfusion is effected by simple intravenous injection. Temperature reactions occurred in only 8 per cent of the cases and they were usually slight. In order to avoid complications the author recommends that blood groups should be watched and that withdrawal as well as transfusion should be done while the persons are still fasting.

Early Lesions of Plumbism.—Otto and Hahn employed Müller's method of capillaroscopy for the detection of early lesions of plumbism. They report studies on fifty workers who for years had been soldering cables and who were not exposed to lead poisoning. Aside from some abnormalities of constitutional origin, the capillaroscopy disclosed no deviations from the normal. The simultaneous determination of the porphyrin content of the urine likewise revealed normal values in these persons. In fifty-five workers who sprayed varnish and who were exposed to lead poisoning, because many of the paints which they had to handle contained lead, the capillaroscopic aspects corresponded with the degree of exposure to lead poisoning. In 50 per cent of these workers there existed slightly atypical forms of the terminal loop with pathologic elongation coiling and winding; in 75 per cent more or less severe contractions of the arterial branch could be observed, and in almost 50 per cent of those with capillary contractions there existed a galloping current and in almost 30 per cent a more granular current. However, the examination of the urine for porphyrin gave better results for the estimation of the degree of lead intoxication in that the urinary elimination of porphyrin was increased in 80 per cent of the cases and in some cases the porphyrin

values exceeded 500 micrograms. In two cases of severe plumbism, capillaroscopy disclosed ischemia in the field of observation in that the arterial branch of the capillaries was greatly contracted. The current was slightly to moderately granular. In these cases too the elimination of porphyrin was rather high. In six cases in which there had been severe lead poisoning, which had cleared up, capillaroscopy disclosed, outside of a few minor contractions and of coiling and the terminal loops, no signs of the former lead poisoning. The changes observed here could be explained on the basis of constitution and age. The porphyrin values of the urine were normal. In experiments on white rats it was found that injection of quantities of lead which were considerably below the lethal dose caused contraction of the capillaries with greater or lesser change in the current. On the basis of these results the authors reach the conclusion that the contractions, coilings and elongations observed in the capillaroscopy of patients exposed to lead intoxication are caused by spasms of the arterial branches of the capillaries. The anemia which develops in lead intoxication can be held responsible for some of the changes on the capillaries but not for all of them. Moreover, it may be assumed with some degree of probability that the capillary changes, which in the beginning are spastic and reversible, later become irreversible and give rise to the frequently observed arterio-capillary fibrosis. The authors stress further that these observations show again that the sensitivity toward lead and the severity of lead intoxication are largely due to the endogenically conditioned vasomotor instability. The majority of patients with lead intoxication belong to the group of persons with vasomotor instability. The authors reach the conclusion that, because of its greater clarity and simplicity, the quantitative determination of porphyrin in the urine is of greater diagnostic value in the early diagnosis of lead intoxication than is capillaroscopy. However, capillaroscopy may prove valuable as a complementary diagnostic procedure and it also provides information about the vascular pathology of lead intoxication.

Insulin Lipodystrophy. L. I. Andres and A. I. Vilkomirskiy.—p. 45.

Hepatolenticular Degeneration.—Tretyakov reports a case in which a boy aged 12 was clinically diagnosed as having the acute abdominal type of hepatolenticular degeneration. The illness began with an acute febrile onset of obscure etiology, accompanied with manifestations of liver cirrhosis and portal stasis (splenomegaly, ascites and anasarca). These were followed by neurologic symptoms of spastic-convulsive lenticular type. The latter resembled tetanoid states but differed from tetany by the absence of mechanical or electrical nerve-muscle hyperirritability and by the presence of pyramidal symptoms pointing to lesions of the central nervous system. The combination of the neurologic symptoms of lenticular type with those of liver cirrhosis permitted the diagnosis of hepatolenticular degeneration. Microscopic studies demonstrated characteristic sclerotic degeneration with an increased growth of cells of type 2 of Alzheimer and typical porous appearance of brain tissue. These alterations were found predominantly in the corpus striatum but were also present in the cerebral cortex, in the region of the aqueduct of Sylvius and in the cerebellar hemispheres. In the author's second case there was a febrile onset in a boy aged 10. Fifteen days later he developed right-sided hemiplegia with aphasia. In the next six weeks the sickness ran a course resembling that of septic endocarditis with an enlargement of the liver and the spleen, terminating in pneumonia. Three days before death the patient had convulsions of extensor-pronator type in both extremities, and opisthotonos. Necropsy revealed a symmetrical subacute degeneration of the lenticular nuclei with formation of cavi-

ties and characteristic microscopic alterations as described by Wilson. The author regards this case as one of subacute lenticular degeneration closely resembling the abdominal type. Because hepatic symptoms in the author's first case preceded the cerebral symptoms by several months, the author feels that the liver lesion was the primary factor and the lesions of the nervous centers secondary. A further proof of the primary importance of the liver and metabolic disturbances is to be seen in the fact that the pathologic alterations of the nervous system are not systematic and are not only localized in the nucleus lentiformis but also involve the cerebral cortex, the substantia nigra, the nucleus dentatus of the cerebellum and the gray and the white matter without definite systematization.

Surgical Treatment of Ulcer.—Knapper reports the results of follow-up examinations on fifty patients who underwent surgical treatment for duodenal ulcer in the years between 1931 and 1937. All the patients had undergone one or several internal treatments before an operation was performed, the author being of the opinion that surgery should be resorted to only after the internal treatment of gastric ulcer has failed. In forty of his cases he performed gastric resection and in ten gastro-enterostomy. In case of duodenal ulcers and in those localized in the antrum pyloricum, he always performed the resection according to Polya, which is a modification of the second operation of Billroth. In ulcers high up on the small curvature he made use of Schoemaker's clamp, which makes possible the resection of a large portion of the small curvature (that containing the ulcer) without having to sacrifice the corresponding section of the large curvature. He completes this resection with a gastrointestinal anastomosis according to Polya, in contradistinction to Schoemaker, who employs the first operation of Billroth for this. Gastro-enterostomy was performed by Knapper always according to the same principle, namely in the form of a retrocolic posterior vertical gastro-jejunostomy. Four of the fifty patients (8 per cent) died as the result of the operation. Of those who survived, forty-four remained free from pain for from one to seven years after the operation and forty were entirely well. In one instance, gastro-enterostomy was without success. Since an interval of from one to seven years does not permit a definite evaluation of the surgical results, the author intends to repeat the follow-up examination after a few years.

Medicoforensic Significance of Starvation.—Stokvis and Naerebout report the case history of a man who was on trial for attempted manslaughter and brutal maltreatment, which he had committed after he had been without food for about a day. The accused did not recall having committed the criminal acts, and investigations revealed that the brutalities represented the release of accumulated feelings of resentment on a day on which the accused had been without food, on which he had suffered from severe headaches and on which he had been

unjustifiedly accused and deliberately made jealous by his fiancée. In connection with this case it was suggested that it is entirely possible that an amnesia exists for acts that have been committed at the time of reduced consciousness and that prolonged fasting results in abnormally low blood sugar values, which in turn create a predisposition for a reduction in consciousness. The authors decided to investigate the possible influence of the reduction of the blood sugar content following prolonged fasting on the state of consciousness. Following a review of the literature on experimental investigations regarding the influence of hunger on the psychic behavior, they describe their own studies on ten healthy persons. 1. They found that hunger is generally followed by a reduction in the sugar content of the blood. 2. Hunger causes a reduction in and instability of the state of consciousness. 3. There exists a certain connection between the reduction in the blood sugar content and the reduction in consciousness. 4. The general reduction of the degree of consciousness as well as the submersion of the consciousness, which occur in healthy persons during a period of starvation, must be taken into consideration in the psychiatric evaluation of delinquents who have committed criminal acts during hunger, regarding which amnesia may or may not exist.

Barium Sulfate Enema in Intussusception of Children.—After pointing out that the reduction of intussusception in children by means of a barium sulfate enema had been suggested as early as 1918 by Langley Porter of San Francisco and that it had been made use of in several countries since 1927, Nordentoft reviews a material comprising 440 cases of intussusception that occurred in Denmark during the years from 1928 to 1935. This survey reveals the increasing use of the barium enema for the examination and treatment of intussusception in children. During the latter half of this period about 33 per cent of all the cases were reduced by barium alone, of the roentgenologically examined about half. The author believes that nearly all forms of intussusception of the large intestine (colic and ileocecal) can be reduced in this manner if they come under treatment within the first twenty-four hours, and provided the attempt is done deliberately and energetically, with the use of an obturating rectal cannula and a constant high pressure. He stresses the importance of the picture of the evacuation and of repeated injection immediately after the fluoroscopic examination. Finally, he discusses briefly the advantages and drawbacks of the roentgenologic method.

SIMPLIFIED INTERNAL FIXATION OF INLAY AND ONLAY BONE GRAFTS

CHAIRMAN'S ADDRESS

O. L. MILLER, M.D.

CHARLOTTE, N. C.

Reviewing indications in general for bone graft surgery of the long bones would be merely repetition of what is already of record in many excellent articles on the subject and available in recent textbooks dealing with the management of fractures.

Good surgeons have already worked out and proved the efficiency of various types of inlay and onlay bone grafts. The physiologic indications and the mechanical application of either type of graft are matters of judgment for the individual operator. Various methods of transfixing a bone graft or bone grafts have been practiced and published. This feature of the operation has been a rather individual thing with surgeons and may still be going through some transition.

Preparation of the host-fragments of bone for the reception of a graft in an ununited fracture is often a tedious and time-consuming dissection. Obtaining a

Fig. 1.—Inlay bone graft securely transfixed with removable Kirschner wire nails.

mass of bone for the graft (which is expected to be something of a splint as well as a graft) is not usually difficult when good instruments are available. However much surgical skill may have been expended in these first two steps, proportionately more is indicated to place the bone graft in proper position effectively and efficiently and maintain it there. In the

Read before the Section on Orthopedic Surgery at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

type of operation in which an inlay bone graft is indicated and used, several methods of fixation have been advocated. Some of these are autogenous dowel pegs, beef-bone pegs and drill holes through the cortex with retaining sutures of wire, catgut or kangaroo tendon. All are moderately tedious and time consuming and some require rather extraordinary skill.

It is expected (though not always true) that when an inlay graft is used the mass of bone will wedge firmly into a groove prepared for its reception. Of course, the graft should fit sufficiently well to prevent its falling into the medulla, but usually some provision must

Fig. 2.—Old ununited fracture of the tibia with inlay bone graft transfixed by means of removable wire nails. Nails removed at end of nine weeks. Graft uniting and bone consolidating at site of fracture.

be made for holding the inlay graft securely to its host if proper surgical requirements are met. The simpler this can be done in keeping with efficiency, the better.

It has been universally conceded that the massive onlay graft is the most physiologic bone graft for its indications. These indications are most frequently encountered in nonunion of the bones of the upper extremity. The operation has been largely taught and popularized in this country by the orthopedic service of the Mayo Clinic and the Campbell Clinic. On seeing my first onlay bone graft operation I was more impressed, though, by the magnitude of the procedure than with its physiologic value. The massive onlay bone graft operation does call for fair skill and its exactions have been largely due to the fact that so much accuracy was required in transfixing the graft, particularly if autogenous bone pegs or bone screws were used. Because the operation of onlay bone grafting appeared so formidable as usually done or described, I had attempted it very limitedly and with misgivings until there occurred to me a quicker and simpler method of transfixing the graft.

With the popularization of the use of metal fixation in bone surgery, particularly the small caliber pins, I first transfixed an inlay bone graft with two removable Kirschner wire nails. This procedure was repeated and

it was found that the pins or nails could be inserted in the briefest possible time and accomplish thorough fixation.

Later I began securing massive onlay bone grafts with removable Kirschner wire nails and found this operation

Fig. 3.—Compound fracture followed by osteomyelitis, sequestration and nonunion. Inlay graft secured by metal nails. Removed at end of ten weeks. Graft taking and fracture defect filling in.

Fig. 4.—Fixation of a massive onlay bone graft by means of removable Kirschner wire nails.

simplified, more quickly done, and the physiologic and functional results satisfactory.

No doubt the autogenous bone pegs or screws, and even the same devices made of beef or sheep bone, have

much to recommend them. At the same time the operations are a bit complicated, particularly when two operating teams are required to function at the same time. Limitation in personnel may sometimes contribute to simplicity in surgery.

Since I first began using Kirschner wire nails for fixation of bone grafts, the classic work of Venable and Stuck on a nonelectrolytic metal for use in bone surgery has come out. Their work would lead one to feel that vitallium metals may be buried in the tissues with impu-

Fig. 5.—Onlay graft in position and nails projecting through the suture line, in position to be removed later.

nity. Either from lack of experience with vitallium screws in bone graft surgery or from a surgical heritage of fear of the use of buried metals of any kind in the tissues, I am still securing grafts with removable metal nails.

When a bone graft is transfixed with metal nails, the nails should be driven through the graft and through the cortex on the opposite side of the shaft. To determine the depth to which the nail is going there should

Fig. 6.—Old fracture of radius with nonunion. Onlay graft fixed with nails which were removed at end of ten weeks. Radius firmly united.

be a set-screw gage attached to the wire or nail at an estimated level. This is the simplest method of measurement. A bone holding forceps, such as illustrated, can be used to control the depth the nail travels. It is not necessary to stagger the nails, though there is no objection to it. They hold securely when placed parallel. The nails should come out directly through the center of the incision if possible. If in closing the skin there is puckering, a transverse slit should be made to relieve it; otherwise superficial healing may be interfered with. Where dissection has been made in scar and granulation

tissue about the site of a bone defect there is necessarily excessive serous ooze which sometimes the tissues are taxed to absorb. Removable pins or nails make ideal drains for this deeply located, excess hemorrhage or secretion and thereby aid wound healing.

Fig. 7.—Ununited fracture of the humerus with pseudarthrosis. Alignment corrected and massive onlay graft secured with Kirschner wire nails. The elbow joint was disorganized and the limited motion threw unusual stress on the fracture line. Nails were removed from a perfectly healthy wound at the end of sixteen weeks. After a reasonable period of protection the bone consolidated firmly at the site of the fracture.

When transfixing a bone graft as outlined here one will find closing the wound a little tedious at first, as the suture material has to be guided between and about

Fig. 8.—Comminuted fracture of the humerus with nonunion in the transverse break at eight months. Massive onlay bone graft was used and a light arm cast worn. The nails were removed at the end of twelve weeks. There was perfect wound healing and firm bony union.

the nails. This, though, is not a serious objection. The operation is simplified in this connection by first clipping the wires an estimated centimeter above the

skin level. While removable wire nails constitute excellent internal fixation, the limb under treatment should be skillfully immobilized by external fixation, usually a plaster of paris cast.

The pins are left in place until by x-ray and clinical examination the graft is found united to the host bone. In my experience the longest period pins have stayed in the tissues before withdrawal has been sixteen weeks. The average time has been from ten to twelve weeks. External protection of the graft may be continued longer. The pins are easily and painlessly removed by rotating and extracting with a drill chuck.

I have now had experience with removable metal fixation of bone grafts for more than two years and in a fair series of cases and feel that the grafts have been securely fixed and their supporting strength less disturbed by small removable nails than by more gross fixation material. In the procedure no foreign material is left in the tissues. In one of the cases the graft was absorbed, owing apparently to some metabolic defect in the tissues. All others have had uncomplicated convalescence.

TREATMENT OF THE ANXIETY STATES

WITH SPECIAL ATTENTION TO CERTAIN PHYSIOLOGIC MANIFESTATIONS

WILLIAM J. KERR, M.D.

PAUL A. GLIEBE, M.D.; MAYO H. SOLEY, M.D.
AND

NATHAN W. SHOCK, Ph.D.

SAN FRANCISCO

Economic and social upheavals in the era since the World War have undoubtedly increased the number of patients who have anxiety states with symptoms that simulate those of serious organic diseases. At least one third of the practice of most physicians consists of such patients. The average physician has little interest in the problems that this group presents and is likely to label them neurosis, neurasthenia, anxiety neurosis or anxiety hysteria and either to neglect the patient or to treat him in the easiest manner possible. Since his treatment is often unsatisfactory, the patient shops around from doctor to doctor until, if he is fortunate, he finds one who will pay enough attention to his symptoms to recognize the physiologic causes as well as the fundamental psychologic factors. Perhaps the increasing popularity of cults has depended largely on the fact that their practitioners at least do something for their followers even though the treatment is not rational. We feel that the term that best describes the nervous phenomena in these persons is "anxiety state" and that the physiologic syndromes associated with anxiety states should be determined accurately in order to complete the diagnosis.

Any situation or group of circumstances, whether real or fanciful, threatening the emotional or social organization of the individual may lead to anxious reactions. Normal anxiety arises from a recognized exciting cause, such as the sensations that any individual will experience after a narrow escape from a potentially serious automobile accident. Morbid anxiety, on the other

Read before the Section on Pharmacology and Therapeutics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

hand, is attached to some idea not related by the patient to its original exciting cause. An illustration of morbid anxiety is shown by the patient who feels that his symptoms have caused him to be inefficient in his work so that he is unable to support the girl he wants to marry, whereas the real cause of his symptoms is a subconscious desire to avoid the marriage—in other words, the patient has reversed the true situation. Of course, these ideas concerning anxiety are not original and are well stated in Henderson and Gillespie's textbook of psychiatry.¹ Just how completely normal and morbid anxiety should be distinguished is difficult to say. However, the group of patients that we wish to discuss fall into the classification of morbid anxiety. Some writers, such as Stekel,² have used the term "fear" to cover what we have termed "normal anxiety," and "anxiety" to mean what we have called "morbid anxiety."

Cannon³ has demonstrated some of the physiologic responses to pain, fear, rage and hunger in animals. Many writers⁴ in recent years have pointed out physiologic mechanisms producing the symptoms in anxiety states in man. Some of these physiologic manifestations are well understood; others have not been

TABLE 1.—Effects of Stimulation of the Central Nervous System

1. Direct nervous effects, through (a) sympathetic: (1) rapid heart rate (2) increased blood pressure	(b) parasympathetic: (1) blushing
2. Hyperadrenism (perhaps accentuated by direct sympathetic stimulation)	
3. Spasm of the gastrointestinal tract, through (a) sympathetic: (1) cardiospasm (2) pylorospasm	(b) parasympathetic: (1) spastic colon
4. Hyperventilation Probably resulting primarily from sympathetic stimulation (symptoms caused by respiratory alkalosis)	

studied completely or are insoluble in our present state of knowledge. One certain point is that overstimulation of the central nervous system (specifically the cerebral cortex) results in a spilling over of impulses into the autonomic nervous system and thus causes the syndromes outlined in the simple schema in table 1. While this schema is not complete, it gives most of the usual effects of stimulation of the autonomic nervous system.

In addition to the syndromes outlined there are hysterical phenomena (the mechanism of which is not even suspected) with such manifestations as amblyopia, anesthesias and paralyses. One might also include the migrainous type of headache as one of the physiologic effects which is not yet understood but which may be due to vascular constriction in areas of the brain. Two or more of these syndromes, representing overactivity of both the sympathetic and the parasympathetic nervous system, may occur coincidentally in one person, a fact that lends weight to the theory of the central

origin of overstimulation. The central nervous system connections of the autonomic nervous system are now well recognized.⁵

The two syndromes that lend themselves most easily to reproduction are the hyperventilation syndrome and hyperadrenism. The hyperventilation syndrome can be reproduced by having the patient overventilate until his symptoms occur and then continue to overbreathe air to which from 2 to 5 per cent carbon dioxide has been added. (A tank of the gas mixture connected to the usual anesthetic bag and mask may be used.) The carbon dioxide mixture relieves the symptoms within about half a minute. The accompanying illustration shows the apparatus used at the University of California Hospital. The effects of hyperadrenism can be precipitated by the intramuscular injection of from 0.2 to 0.3 cc. of a 1:1,000 solution of epinephrine hydrochloride. The effects last only a short time, so that epinephrine may be given safely unless the patient has coincident cardiovascular disease. A similar method of approach may be used in cases of parasympathetic overactivity.⁶ The physician should explain in simple, nontechnical language the physiologic changes the patient undergoes as his symptoms develop. If possible, this should be done soon after these therapeutic tests so that the patient remembers the exact sequence of events.

As soon as the patient realizes that the doctor understands the immediate cause of his difficulties, he is much more amenable to procedures directed toward uncovering the cause of his anxiety. Experience has shown that symptomatic treatment without an attempt to relieve the maladjustments that are responsible for the excessive cortical stimulation is unsatisfactory for both patient and physician. These maladjustments frequently can be recognized and corrected by the general practitioner or internist. A larger group, including the patients who shop around from physician to physician, have deep-seated conflicts. For these the help of a psychiatrist who is interested in anxiety states as well as in the major psychoses is required.

In the psychiatric approach, the patient should be considered as a person who is ill physically as well as emotionally. The rapport or positive transference to the person of the physician is essential in the early phase of any modern psychiatric treatment. The advantage of recognition by the physician of the exact physiologic cause of the symptoms in any patient lies in the fact that the physiologic mechanism can be proved by reproduction of the symptoms and the patient's confidence thus gained. There is then no necessity of telling the patient that he is "just nervous." The doctor must realize that such symptoms may be far more uncomfortable than those of many serious organic diseases. Unfortunately a certain number of persons who have their physical symptoms relieved will consider themselves as cured and hence will see no reason for discovering the psychologic factors in their illness. The initial resistance of such a patient, which unconsciously has thwarted the psychologic approach, is then reinforced by the conclusion on the part of the patient that the original cause of his trouble must have been physical since he had been relieved with medicines.

The basis of all psychiatric investigation is a good history, which should include, besides the usual factual

material, his loves, ambitions and frustrations. From the history, emotional responses and the content and interpretation of dreams, one is led to the cause of the psychologic maladjustment. When the patient recognizes the relationship of his conflicts to his physical symptoms, he usually recovers. It must be admitted, however, that there will always be patients who are "psychopathically and protoplasmically" inferior and therefore not amenable to psychiatric treatment, who must be treated symptomatically as their various complaints are brought to the doctor.

During the early stages of treatment, most patients with anxiety states require drugs that depress the central nervous system. The bromides, phenobarbital and isoamylethylbarbituric acid (amytal) are particularly effective because they depress the cerebral cortex.⁷ Dosages range from 1 to 1.5 Gm. of sodium bromide three times a day, from 0.015 to 0.045 Gm. of phenobarbital three times a day and from 0.045 to 0.06 Gm. of amytal three times a day. Other barbiturates act mainly on the hypothalamic region; thus, while they may decrease stimulation of the autonomic nervous system and relieve certain peripheral symptoms, they do not relieve so effectively those symptoms of anxiety directly referable to the cerebral cortex. It should be remembered that anxious persons require larger doses of these drugs for cortical depression than do normal individuals. Dr. Chauncey D. Leake has illustrated this principle excellently in a diagram which he uses for teaching purposes in his course in pharmacology at the University of California. This diagram (table 2) emphasizes the fact that, when any central nervous system depressant is given, a larger dose is necessary to produce depression from the excited state than from the normal state.

Other central nervous system depressants, such as chloral hydrate, may be substituted in order to circumvent the danger of chronic toxicity or habit formation. Some writers⁸ feel that the addition of one of the coal tar derivatives increases the effectiveness of the barbiturates. It should be mentioned here that the advertised advantages of many of the proprietary soporifics do not justify their excessive cost.⁹

The soporifics play a double role in the treatment of the anxiety states. They prevent the overflow of impulses into the autonomic nervous system and raise the sensory threshold so that, even if there is some autonomic overactivity, the resulting sensations cause less discomfort. This is important since at the present time there is, for example, no method by which one can with safety paralyze the sympathetic ganglions (nicotine-like action) or paralyze the myoneural junctions of the sympathetics. There is no other method of decreasing sympathetic activity except the very radical one of denervation of the adrenal glands. In our opinion this type of operation disregards the etiology of the adrenal hyperfunction in anxiety states. In hyperadrenism, then, one must resort to relief of anxiety and to central sedation.

Pylorospasm and cardiospasm, though they also may result from sympathicotonia, require specific treatment. It seems to us that here, again, the origin is more frequently anxiety states than is commonly recognized and that the dietary measures usually prescribed are inadequate.

The use of the atropine series is rational only when the chief discomfort arises in hyperperistalsis proximal to the spastic sphincter. In the sphincters themselves the paralyzing of the parasympathetic nerve endings accentuates the sympathetic effects of constriction. One possible reason for administering the atropine group is that, with parasympathetic paralysis, loss of the opposing action to the sympathetics may break a vicious cycle. However, if one may cite an analogy with skeletal muscle, the loss of function of groups of muscles which have opposing actions to others (in a state of "spastic paralysis") causes contractures of the latter groups. Drugs such as glyceryl trinitrate and other nitrites which relax smooth muscle may be prescribed.

On the other hand, the atropine series is especially useful in the treatment of spastic colon, because these drugs paralyze parasympathetic nerve endings. A new

Apparatus used at University of California Hospital.

and promising type of drug is trasentin (diphenylethyl-dimethylaminoethanol hydrochloride). The usual dietary measures are not directed against the fundamental pathologic physiology. Spastic colon rarely is found in an individual having normal psychologic adjustments; therefore, psychiatric measures combined with symptomatic treatment will lead most directly to successful results.

The work of Gordon Alles and others¹⁰ is paving the way to advances in the treatment of patients with hyperfunctioning autonomic nervous systems. For example, at the present time there are few drugs that exert a selective action on any part of the autonomic nervous system. Sufficient atropine to relax a spastic colon may cause uncomfortable dryness of the mouth and perhaps blurring of vision. The ideal drug for parasympathetic inhibition of the colon acts mainly on the colon without producing other side-reactions. Dr. Alles already has been able to prepare phenethylamines with which, in suitable dosages, central stimulation is minimal whereas rises in blood pressure are great. Each

step in the development of such drugs teaches us more about chemical constitution in relation to physiologic action, so that eventually we may be able to synthesize drugs that have selective actions on certain autonomic functions. It may be stated here that the inhibiting drugs are far more important than the stimulating ones, but unfortunately the latter are much more thoroughly understood.

In hyperventilation syndrome the benefits of rational therapy are realized better than in any of the other syndromes of the group we are discussing. The patient can be taught to breathe abdominally. Although the respiratory rate is increased by this measure, the total ventilation with abdominal breathing is far less than it would be either with chest breathing or with chest and abdominal breathing combined. Sedatives may be prescribed to raise the patient's threshold to all stimuli. Ammonium chloride in divided doses up to from 3 to 6 Gm. daily tends to produce an acidosis, so that even the original degree of hyperventilation will not shift the p_H to the point of production of tetany. Hydro-

niton of the physiologic factors producing the symptoms in this group of patients leads to rational symptomatic treatment as well as greater ease in the psychiatric treatment of the underlying causes of anxiety.

ABSTRACT OF DISCUSSION

DR. EDWARD G. BILLINGS, Denver: At the University of Colorado School of Medicine and Hospitals, more than one half of anxious patients have been misdiagnosed as having hyperthyroidism, peptic ulcer and other organogenic disorders. They first become tense when the issues of life begin to diminish their margin of security. This usually occurs not because they are inferior but more as a result of the way they understand and run the business of living. Then, when tense, any type of experience, usually one either actually or potentially emotionally charged, may precipitate an attack of anxiety. The first step in therapy is to elicit the facts of the case by following a common sense and sympathetic procedure of history taking and examination of the mental status. A physical examination should be done in every case. About 20 per cent of these patients will probably present evidences of some somatic pathologic condition. Often these bodily disorders are but incidental to the psychiatric problem. It is of the utmost importance that such bodily disorders be evaluated for what they are in relationship to the total problem and to the total reaction, lest they act more or less as proverbial "red herrings" and distract the physician from the main issue at hand. I should like to reemphasize that we should not use solely the method of exclusion in arriving at a psychiatric diagnosis. It is too time consuming and too expensive both to the patient and to the physician. Barbitol in small doses, from 32 to 64 mg. from once to three times a day, is in my experience more effective in reducing the psychobiologic tension than some of the other more fashionable drugs. Barbitol in small doses reduces the tension without slowing the patient's thinking. If the anxious patient's thinking is slowed up he feels more insecure and therefore more anxious. Empirically I have found that extract of European hawthorne from 10 to 20 minims (0.6 to 0.12 cc.) three times a day also seems to be somewhat effective in diminishing the physiologic repercussions that occur in anxiety, particularly when they arise on the bases of an existing hypersympathicotonia. Regarding the hyperventilation syndrome that the authors outlined, I have found that very few anxious cases responded with tetany or marked alkalosis, at least on hyperventilation, unless the patient was very suggestible and unless a considerable amount of positive suggestion was utilized along with the hyperventilation. I should therefore like to ask the authors whether they feel that suggestion does play some role in the tetany-like syndromes that develop during the hyperventilation of some of these patients.

DR. FRED M. SMITH, Iowa City: The authors have discussed an extremely important type of case. It is very common and often presents a difficult problem in treatment. Many of these patients come to the physician because of some form of abdominal distress which may closely resemble almost any organic disease of the abdomen. The x-ray examination of the gastrointestinal tract frequently discloses a hypertonicity and increased peristalsis of the stomach, perhaps pylorospasm, occasionally cardiospasm, and commonly a spastic state of the colon. Furthermore, there is not infrequently a spasm of the sphincter of Oddi producing temporary interference with the emptying of the gallbladder. It is obvious that these patients should be carefully studied in order to rule out organic disease. After this is accomplished the situation should be carefully explained to the patient. In fact, this is one of the first steps in the treatment. Ordinarily a simple general diet will suffice. One should make certain that the dietary requirements are fulfilled. Relaxation and ample sleep are essential. Constipation is frequently present and should be controlled as far as possible by simple measures such as small amounts of liquid petrolatum supplemented by glycerin suppositories. Most of these patients can be handled by the sympathetic and understanding practitioner and in general the results are gratifying.

TABLE 2.—Dose of Soporific Necessary to Produce Depression in Various States of Central Nervous System Activity*

Excitement:	Faster reaction time than normal	Increased muscle tone, respiration, pulse rate, and so on	Dose of Soporific Required to Produce Depression
Normal:	Average reflex reaction time	Average muscle tone, respiration, pulse rate, and so on	
Depression:	Slowed reaction time	Decreased muscle tone, respiration, pulse rate, and so on	
Delirium:	Uncoordinated reflex response	Variable muscle tone, respiration, pulse rate, and so on	
Anesthesia:	No reflex response	Markedly decreased muscle tone, with respiration and pulse rate as in deep sleep, and so on	
Coma:	Loss of muscle tone, very slow respiration, and so on	

* From lecture notes of Dr. Chauncey D. Leake.

chloric acid and acidifying diets are helpful. Finally, removal of the cause of anxiety by the psychiatrist completes the treatment. Recent work at the University of California indicates that effort syndrome¹¹ is really caused by hyperventilation and should be handled therapeutically as outlined for the treatment of the hyperventilation syndrome.

A warning should be given concerning the diagnosis of the anxiety states. Whenever there is possibility of the existence of any organic disease, thorough studies of the patient should be made. While most patients with cancerphobia do not have carcinomas, there is always the possibility that their fears are based on fact. Likewise in effort syndrome, valvular or myocardial damage should be ruled out by electrocardiograms and chest films together with careful physical examination. In other words, the burden of proof is on the doctor who states that no organic disease is present.

SUMMARY

A large proportion of all patients seen by doctors have anxiety states. In treatment, both symptomatic and psychiatric measures should be used. The recog-

DR. WALTER FREEMAN, Washington, D. C.: In the history of these patients there is often to be found some precipitating factor. A disturbing circumstance like paroxysmal tachycardia will immediately focus the patient's attention on his heart or the sensation in some other part of the body. Fatigue and fright are two factors in inducing a state of anxiety. Fatigue has a peculiar way of increasing preoccupation with bodily functions. It lowers the threshold to sensibility and brings about overalertness. It produces a hypertonicity of smooth muscle, as has been mentioned. These two factors contribute to the exaggeration of the sensations that are being received by the patient from his own body. Now, then, we get into a vicious circle. Here is a patient already fatigued; he is alarmed; he is anxious. His body mechanisms are not working well. His attention becomes fixed on those visceral phenomena and further fatigue results. The careful taking of the history, the detailed examination, the reassurance, the reproduction of the symptoms and the explanation of their origin will reassure the patient. But sometimes the tension is so great that we are unable to overcome it. How do we break through this vicious circle? Of drugs that paralyze the sympathetic nervous system, alcohol is probably the finest (taken internally of course) but the effect does not last, and alcohol brings in its train certain other symptoms that are just as bad. Alcohol is not to be recommended, although it will temporarily abolish this hypersympathicotonia. Rest is important, but the patient says, "Doctor, when I lie down I feel as though I were going to jump out of my skin." Exercise is useful. I know individuals who can't rest at night unless they walk 5 miles a day. The inner tension has to find expression. Hysterics is a grand way but is not socially acceptable, just like alcohol. Patients quiet down after an attack of hysterics and convulsions. The great muscular activity possibly brings about therapeutic acidosis. Metrazol convulsions are sometimes useful in severe anxiety states. The shock method breaks through the vicious circle and produces relaxation and relief of tension. There is a physical basis for these anxiety states. Usually they can be adequately handled in general practice and physicians are encouraged to treat these patients. But there are some that do not react to the kindly, thoughtful, considerate and effective treatment of Dr. Kerr and his co-workers; these are the types that probably need even sterner measures.

DR. WILLIAM J. KERR, San Francisco: Hyperventilation occurs in most of these patients under our observation. If you ask them if they sigh, which they do under observation several times a minute, they may say "I don't know that I do, but my family or my friends say that I do." You will find this to be more or less generally true in this group, and the symptom is not limited to those with well organized psychopathic states. The most important thing in treatment is to demonstrate to the patient, by having her hyperventilate for half a minute or longer (sometimes it requires two or three minutes) it will reproduce almost exactly and repeatedly the symptoms which brings her to the doctor. Then you may explain exactly how the rest of the picture has been produced. I don't believe it is a matter of suggestion. Dr. Smith emphasized the gastrointestinal side. All of us see patients referred from doctors in all the special fields of medicine, including many who have been operated on for undiagnosed or misdiagnosed conditions. Many bear multiple scars on the abdomen; many have had repeated cystoscopies, when they had nothing but a spasm of the neck of the bladder. These people have not only physical scars but in my opinion also psychic scars, and some of them are not reversible. Many of these patients are finicky eaters; they can't take this and can't take that, and many have eliminated almost everything from their diet. But see one of them when he goes to the mountains or the seashore for his vacation. He will eat baked beans, hot baking powder biscuits and hot cakes. Then you will know that his condition is on a functional basis. The precipitating factors Dr. Freeman mentioned are important. Many of these people who have a low threshold, either inherited or acquired, probably inherited more often, will break under some ordinary stress or strain and from that time on will be in great trouble. Yet one may

be able to correct the problem for them, give them understanding, give them help, and, until some other stress comes along, they are perfectly normal people. I believe we can say that we have "cured" many of these patients who otherwise would be hopeless wrecks for the rest of their lives. We have restored people to normal social life. Sometimes it may require the help of several physicians and members of the family working together. In our studies we have tried to apply all the knowledge that we could bring to bear from every field, that of the clinician, the physiologist, the psychiatrist and the chemist. I believe that we are all on the way to solving it. There is much that remains to be done.

DERMATITIS OF THE EAR

HENRY L. WILLIAMS, M.D.

HAMILTON MONTGOMERY, M.D.

AND

WILLIAM N. POWELL, M.D.

ROCHESTER, MINN.

Dermatitis of the ear has been a subject of difference of opinion between dermatologists and otologists with regard to causation and treatment. Thus many otologists would emphasize the factor of fungal infestation in the causation of dermatitis of the external ear whereas according to the dermatologist dermatitis involving the external portions of the ear and retroauricular region may result from many diverse factors.¹ It is obvious that there must be an empirical background for these divergent opinions, the probability being that the relatively simple and easily cured cases have remained in the hands of the otologist who first saw them while the refractory cases have been referred to the dermatologist.

It is not our purpose to comment on the obvious cases of contact dermatitis of the ears from sensitivity to nickel on spectacle bows, to fur pieces, to silk, to wool or to various medications used in treatment of the hair and scalp, including dyes and local applications to the ear canal, or to consider secondary involvement of the ear in the case of universal or partially generalized dermatitis including atopic (allergic) dermatitis. Various chronic dermatoses in which involvement of the external ear is common, such as lupus erythematosus or psoriasis, will not be discussed.

Ordinary dandruff (seborrhea sicca or seborrhea oleosa) occurs primarily in the scalp but may involve the ears, flexural surfaces and folds in the form of a seborrheic eczema (Unna)² that is, seborrheic dermatitis. Several authors recently have questioned whether many of these cases have not been cases of streptococcal dermatitis starting with involvement of the retroauricular region and then showing patches of intertrigo elsewhere on the body.³

Read before the Section on Dermatology and Syphilology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

LITERATURE

Recent investigations have indicated that streptococci are rarely to be found in normal skin even in the scalp or retro-auricular regions.⁴ They also have indicated that the same is true to a lesser degree of staphylococci in contrast to micrococci and certain types of fungi which usually are regarded as being nonpathogens. Older investigations, such as those of Photinos,⁵ who found streptococci present about the nose and in the retro-auricular region in 64 per cent of a series of cases, are difficult of evaluation, as most of the patients had either seborrhea or acne and thus could not be regarded as having normal skin.

The tendency to ascribe dermatitis of the ear to fungal infestation has recently been particularly emphasized in otologic literature. McBurney and Searcy⁶ and Gill⁷ stimulated interest in the fungi as etiologic agents in external otitis. Whalen⁸ in 1938 stated that dermatitis of the ear could be healed in nine days by following his method of eradicating pathogenic fungi and could be prevented from recurring by the oral ingestion of potassium iodide for thirty days.

On the other hand, Greaves⁹ in 1936 was unable to demonstrate fungus in seventy-five cases of otitis externa by smear, hanging drop or culture. He stated that the etiologic agent in otitis externa is doubtful. Staphylococci and streptococci were extremely rare, but all the cases showed the presence of a gram-negative, motile, pigment-producing bacillus of the pseudomonas or pyocyanus group. He thought it probable that this organism was an accidental secondary invader in his cases. Sabouraud,¹⁰ as far back as 1900, was inclined to attribute some of these lesions of the ear to the streptococcus. Mitchell¹¹ in 1937 in a well illustrated article found himself in complete accord with the observations of Sabouraud. He was able to demonstrate streptococci in the serum from fissures and in the squama-like crusts from the ear. By cultural methods especially adapted to the growing of the streptococcus he was able to obtain these organisms on culture. In investigations of dermatides of the skin it has been impossible to fulfil Koch's postulates. In many cases the use of special cultural methods directed toward the demonstration of certain organisms might have prevented the recognition of other organisms present.

MATERIAL STUDIED

Thirty-four routine cases in which the patient came to the Department of Otolaryngology or of Dermatology of the Mayo Clinic with a complaint of dermatitis of the ear were studied by the otologist with especial reference to disease in the external auditory

canal, by the dermatologist with reference to retro-auricular dermatitis, and for other manifestations of cutaneous disease in the scalp and elsewhere on the body, and by the bacteriologist in an attempt to isolate and to identify any bacteria or fungi present which might be an etiologic factor in producing the lesions.

CLINICAL DATA

We were unable to classify from the clinical characteristics alone the dermatoses present in our cases as belonging to a specific type of dermatitis. We saw no borderline cases between so-called seborrheic eczema and psoriasis which may involve the ear and the ear canal. More than 80 per cent of the patients were women. The following brief case histories are presented to illustrate the complexity of the problem:

REPORT OF CASES

CASE 1.—A woman aged 52 gave the history of a chronic discharge of the right ear since childhood. She reported that since an acute exacerbation of the otitis a year previously she had had an itchy, scaling and weeping dermatitis involving the external right ear and the nose. A biopsy showed marked dilatation of the superficial vessels and absence of fat in the stratum corneum. On culture of the lesion, both *Streptococcus haemolyticus* and *Staphylococcus aureus* were found to be present. This patient had consulted several dermatologists during the year before admission to the clinic without relief of her symptoms.

Although she had not been conscious of a discharge from the ear for the past year, examination of the ear disclosed a fistula into the attic. A roentgenogram showed the presence of a large cholesteatoma in the right mastoid. A Bondy type of modified radical mastoidectomy was done with preservation of the matrix of the cholesteatoma. Convalescence was without incident and the dermatitis rapidly disappeared with routine postoperative treatment of the large cavity that necessarily resulted from the operation.

CASE 2.—A woman aged 44 stated that, starting a year previously, a pruritic lichenoid dermatitis of the forearms and wrists gradually spread to involve the upper arms, the neck and finally the right ear, where it became localized. A subacute dermatitis involving the right ear canal and the rest of the external ear and extending slightly onto the neck below the ear was found. Treatment of the ear canal was instituted by cleansing and the use of phenylmercuric nitrate, of merthiolate and thymol mixture and of thymol iodide dusting powder. With the use of each of these drugs the lesion in the ear canal cleared up with amelioration of the dermatitis of the concha, but while still under treatment the dermatitis would again extend into the ear canal from the concha. The patient was found to have a questionable sensitivity to mercury but did as badly on thymol iodide as on the mercurials. With the use of wet dressings of aluminum acetate followed by crude coal tar the dermatitis rapidly cleared up over the whole of the external ear except the external auditory canal. With the disappearance of the dermatitis over the rest of the external ear, however, the lesions in the canal responded to simple cleansing. Culture from the lesions revealed the presence of *Streptococcus viridans* and *Monilia parapsilosis*. In this case there were factors of neurodermatitis and contact dermatitis, yet cultures were positive and the lesion healed under application of coal tar ointment.

CASE 3.—A woman aged 28 complained that an earache, which she ascribed to a cold, had been present on the right for three days. On examination of the ear the skin of the right external auditory canal was found to be reddened and swollen and the ear drum and the canal medial to the isthmus were covered with a grayish white pseudomembrane. The pseudomembrane was removed and sent for culture, *Aspergillus fumigatus* being found. The ear canal was carefully cleaned and phenylmercuric nitrate dusting powder blown into the canal. The external auditory canal had resumed a normal appearance by the third day and treatment was discontinued. There has been no recurrence in two months.

CASE 4.—A woman aged 45 stated that for the past six years she had been troubled with an itching dermatitis of both ears. Examination revealed an erythematous, moist, scaling dermatitis with crusting and fissuring, involving the entire external ear and postauricular fold on both sides with the exception of the external auditory canals (fig. 1). The lesion was thought to be typical of a streptococcal dermatitis, but on culture *Staphylococcus aureus* and a diphtheroid bacillus were found. A specimen taken for biopsy revealed a histologic picture suggesting a seborrheic or eczematoid dermatitis (fig. 2). The patient was unable to stay for treatment but was given an alcoholic lotion for the scalp and a 2 per cent solution of gentian violet for the dermatitis of the ears. The patient reported no improvement in the condition of the ears.

CASE 5.—This patient complained of a dermatitis of both ears, the face and the eyelids, which had been present for six months. An oozing edematous crusting dermatitis involving the lobules of both ears, the forehead, the upper lids and the bridge of the nose was found, which was thought to present an appearance characteristic of streptococcal dermatitis. On culture of the lesions, *Staphylococcus aureus* was found. The dermatitis cleared up rapidly with the use of a mild ointment. In three months, however, a generalized, moist dermatitis, suggestive of an atopic eczema, developed. This was complicated by a subacute purulent mastitis with multiple abscesses scat-

Fig. 1 (case 4).—Dermatitis confined to the external ear with weeping and fissuring suggestive of streptococcal dermatitis. *Staphylococcus aureus* and a diphtheroid bacillus were found on culture.

tered throughout the left breast. Culture from the breast also revealed the presence of *Staphylococcus aureus*. After a simple amputation of the breast the dermatitis cleared up rapidly with local applications.

CASE 6.—A woman aged 38 had had a dermatitis back of the ears since childhood. For the two years previous to admission to the clinic she had had attacks of fall hay fever. Intradermal tests revealed positive reactions to giant, small and western ragweed, to orris root and to egg white. Examination of the ears showed a moist scaling dermatitis on the postauricular region of both ears (fig. 3). A biopsy specimen was not diagnostic. Culture of the lesions revealed the presence of both *Streptococcus haemolyticus* and *Staphylococcus aureus*. The lesions showed a rapid response to treatment with a mixture of a 1:1,000 solution of merthiolate and a 2 per cent solution of thymol.

CASE 7.—A woman aged 37 had had generalized infantile eczema until the age of 7. She was free then until four years ago, when a severe dermatitis recurred over the hands, the forearms, the left popliteal space, the face and the ears. She had had fall hay fever and perennial vasomotor rhinitis for many years. On cutaneous testing the patient gave grade 4 reactions to the cereal grasses and to ragweed, on a basis of 1 to 4, and also had a strongly positive reaction to milk. About a year ago the dermatitis of the ears became much more severe. The skin of the ears was erythematous and edematous, with oozing

and crusting. The external auditory canals were swollen shut and were exquisitely tender. Treatment of the ears with routine ointments gave no relief. On culture of the lesions *Streptococcus haemolyticus*, *Streptococcus viridans*, *Staphylococcus albus* and *Escherichia coli* were found. Biopsy specimens from the retro-auricular region and the left thigh showed similar changes suggestive of a seborrheic dermatitis. Attention to cleansing the external auditory canal and the alternate use of

Fig. 2 (case 4).—Acanthosis, papillomatosis and extravasation of leukocytes through the epidermis. Clumps of cocci were demonstrated in the stratum corneum.

phenylmercuric nitrate dusting powder and of the merthiolate and thymol mixture caused a complete relief of the symptoms and a disappearance of the dermatitis as they related to the ears in less than a week. The generalized dermatitis has remained the same, but the patient has had no recurrence of the dermatitis of the ears in two months.

CASE 8.—A woman aged 65 complained of pruritus vulvae and ani and scaling behind the ears of a duration of three months. There was a marked dry scaling of the scalp. The patient responded to treatment but returned four years later, at which time there was a marked, moist, oozing dermatitis involving the scalp, ears, side of the neck, axilla, breasts, navel,

Fig. 3 (case 6).—Moist, weeping, crusting dermatitis confined to the retro-auricular area and adjacent scalp.

groin and perineum. The whole of the external ear was involved. The clinical picture was that of so-called streptococcal dermatitis. Cultures from all the regions involved revealed *Streptococcus viridans*, *Streptococcus haemolyticus* and *Staphylococcus aureus*; the last only was found beneath the right breast. The patient responded promptly to the use of 2 per cent crude coal tar ointment.

PATHOLOGIC STUDIES

Specimens for biopsy were removed by cutaneous punch from the retro-auricular regions in seven of the cases in this series. Specimens for biopsy taken from various regions in the body in thirteen other cases of

so-called seborrheic dermatitis were reviewed and the pathologic changes found to be comparable to those seen in this series.

The pathologic changes found in dermatitis of the ears are not diagnostic, features suggestive of contact

and atopic eczema and of localized neurodermatitis being present in varying degrees. There usually is a varying degree of acanthosis (thickening of the prickle cell layer) and papillomatosis with dilatation of the superficial vessels and extravasation of leukocytes and lymphocytes about the vessels. Occasionally there is slight thickening of the walls of some of the vessels as the result of edema of the endothelial cells. In the acute exudative phase, extravasation of leukocytes and lymphocytes occurs through the epidermis together with spongiosis and formation of vesicles, and in these vesicles or vesicopustules clumps of cocci are frequently to be found.

Frozen sections stained for fat revealed little if any amount of lipid in the stratum corneum and none in the rest of the epidermis, which is in contradiction to the statements in the German literature,² including those of Gans.¹² Seborrheic dermatitis has always been regarded as a greasy process and Marchionini¹³ recently demonstrated an increase of cholesterol and total lipoids in the superficial layers of the skin and so-called seborrheic regions of the body. We were unable to make use of his method or to make any determinations in regard to the p_H of the skin. Seven of ten cases in this series in which determinations for blood lipoids were made were within normal limits. In one case there was an increase of lipoids associated with a cholesteatoma in the mastoid, in another case slight increase of lipoids was associated with a low basal metabolic rate and in a third case there was a slight increase of lipoids in a woman aged 54 with a disease of the gallbladder.

BACTERIOLOGIC METHODS

In our cases material from the lesions of the external ears and in certain instances from dermatitis elsewhere on the body was studied both by direct microscopic examination and by cultural methods. The affected regions, after very light sponging with 50 per cent alcohol followed by drying with sterile gauze, were scraped with a sterile sharp-edged wire loop. The material thus obtained was examined directly as dried smears stained with Gram's stain, as moist preparations in 30 per cent solution of sodium hydroxide and as moist preparations in equal parts of Loeffler's methylene blue and glycerin. Cultures were made in tubes of dextrose brain broth and on slants of Difco wort agar. Two dextrose brain broth tubes were inoculated in a routine manner, crystal violet in a concentration of 1:200,000 being added to one as suggested by Haxthausen.¹⁴ After incubation at 37 C. for from eighteen to twenty-four hours the brain broth cultures were examined microscopically and any organisms found were plated out in blood agar or other appropriate mediums for identification. Except for Difco wort agar, special mediums for isolating fungi were not employed.

With the exception of *Pityrosporum ovale*, no organism was identified, without cultural proof, solely on the basis of its morphology in preparations made directly from the lesions. Mass-forming cocci were divided into micrococci and staphylococci on the basis of morphology, according to the criteria of Thompson.¹⁵ The staphylococci were classified further on the basis of pigment

formation. Streptococci were classified according to their action on blood agar plates. Other organisms were identified by their morphology and by their behavior on appropriate mediums. A summary of the clinical and bacteriologic data for each patient is given in the accompanying table.

TREATMENT

Suggestions for treatment have been as manifold as have been suggestions regarding the cause of the condition. In general, greases would seem contraindicated in treatment of the ear canal. Yet Mitchell¹¹ has reported excellent results in the cases in which he demonstrated streptococci from the use of 2 per cent ammoniated mercury in petrolatum. He warns against using mercury in any form without first patch testing the patient with 3 per cent ammoniated mercury ointment to detect sensitiveness to mercury. In the treatment of our group of cases we made an attempt to assess the value of a few of the suggested remedies. We used the following remedies: a mixture of equal parts of a solution of 1:1,000 merthiolate and a 2 per cent solution of thymol in 95 per cent alcohol; 2 per cent thymol in 95 per cent alcohol; metacresyl acetate; thymol iodide dusting powder; 1:1,250 phenylmercuric nitrate in a base of boric acid, zinc oxide and a talcum, and a mixture of 1:1,000 solution of mercury bichloride, boric acid and alcohol. There was a group of cases that responded favorably to local treatment of the external auditory canal.

We formed the working hypothesis that the irritating factor, of whatever nature, had as its pabulum the detritus in the external auditory canal and that the first requirement for treatment should be the most careful attention to cleansing the external auditory canal and drum of any foreign material. Difficulty was occasionally experienced in removing debris medial and inferior to the isthmus where in certain ears a relatively deep pit is formed. In addition to removing debris, attention was given to removing any adhering crusts or scales underneath which possibly causative organisms of whatever nature might find protection.

In eighteen of the twenty-five cases with involvement of the external auditory canal this careful handling of the external auditory canal seemed to be the important factor in clearing up the dermatitis not only in the external canal but in the rest of the external ear as well, with little difference in favor of any drug used. However, thymol iodide dusting powder, phenylmercuric nitrate powder or a mixture of boric acid, mercury bichloride and alcohol had apparently an equally favorable effect, the lesions disappearing in from three days to a week. In certain isolated cases the use of mercury bichloride or phenylmercuric nitrate produced a definite flare-up in the condition. These patients were subsequently patch tested to one or another mercurial and found to react positively. In certain other cases, however, treatment of the external auditory canal seemed to have no effect whatever on lesions of the concha and other portions of the external ear, the canal in fact seeming to be reinvolved repeatedly by an extension from the concha.

Patients who did not respond to treatment of the external auditory canal by the use of antiseptics or in whom additional areas of the skin became involved were referred to the dermatologic section for treatment.

In very acute dermatitis of the ears, wet dressings of 0.5 per cent solution of aluminum subacetate and boric

acid wet dressings were used. The external ear in the so-called streptococcic types was treated with gentian violet or ammoniated mercury preparations. In chronic types of dermatitis where there was an element of local neurodermatitis or atopic eczema, 3 per cent ichthammol in zinc oxide ointment, 2 per cent crude coal tar and preparations containing salicylic acid and sulfur were used.

SUMMARY AND CONCLUSIONS

From consideration of dermatitis of the ear with involvement of the external auditory canal we believe:

1. The fact that streptococci or staphylococci or both were demonstrated in many of the cases in this series suggests that they might be of etiologic significance. We were unable to establish definitely in any case that the dermatitis was primarily on a bacterial, fungal or allergic basis. It will be necessary therefore to classify our cases as idiopathic dermatitis of the external ear.

2. Involvement of the external auditory canal is of primary importance in the majority of cases of dermatitis of the ear, with certain notable exceptions. These exceptions are the basis for the difference of opinion as to the curability of dermatitis of the ear that exists between the otologist and the dermatologist.

3. Careful attention to cleansing the external auditory canal is the factor of primary importance in certain cases. The selection of drugs for treatment is of distinctly secondary importance.

4. No general formula of treatment can be applied to this condition, but a variety of drugs should be at hand to avoid the hypersensitive reaction produced in certain individuals by any one of the drugs ordinarily employed.

5. Some cases require the active cooperation of the dermatologist and the otologist to effect a cure. Dermatitis of the ear, where the external auditory canal is not involved, lies wholly in the province of the dermatologist.

6. The amount of dry or oily seborrhea (dandruff) did not correspond to the degree of involvement of the ears or ear canal, although in a few cases the external ear appeared to be involved by extension of a marked seborrhea.

7. Retro-auricular dermatitis, of either the dry or the moist type, and either independent of lesions or associated with lesions elsewhere on the ear and other parts of the body, frequently was associated with positive cultures for streptococci or staphylococci or both. A moist exudative dermatitis was not necessarily indicative of the presence of streptococci.

8. Further histopathologic and histochemical studies should be made in regard to the older concept regarding an increase in lipoids in the skin, which was not borne out in this series.

ABSTRACT OF DISCUSSION

DR. JAMES H. MITCHELL, Chicago: In 1936 before this section I read a paper on "Streptococcic Dermatoses of the Ear." From talks with various colleagues it appears that I am trying to make streptococcic dermatitis out of everything about the ear. Nothing could be further from the fact. Those cases were treated as dermatitis and I missed it completely. Since then I have studied quite a number of cases, some of which are so obvious that it doesn't require any expert judgment to see the origin of the dermatitis about the ears. I don't wish to give anybody the impression that all of these cases are streptococcic. The question remains as to what role the staphylococcus may be playing. This ubiquitous organism is always present, and it is impossible to make any kind of cultures from the skin without getting it, unless it is inhibited with gentian violet or something else. So that it is very difficult

to say what role the staphylococcus may have played. In the cases that I have studied I made a careful effort to find fungi but I haven't found any. As regards treatment, ammoniated mercury in absence of sensitiveness is of value and the x-rays in conjunction with it are also of benefit. Gentian violet instilled into the ear is of benefit in many cases and always tolerated, practically. But some of them in spite of these various efforts have gone on and given me a great of trouble. I still feel that the streptococcus is a very active etiologic factor and physicians who are not familiar with the work of Milian would do well to look it over. He has many fine pictures of all kinds of lesions about the large folds of the body, the ears and in the scalp. The streptococcus can imitate pityriasis steatoides or sicca to such a degree that one cannot tell the difference unless one makes careful microscopic examinations and cultural examinations as well. The organism can be very plainly demonstrated in the scales along with *Pityrosporum ovale*. If *Pityrosporum ovale* is the active factor, streptococci will not be found. If the streptococcus is the active factor, *Pityrosporum ovale* will be limited in number.

DR. M. F. ENGMAN, St. Louis: It is very difficult to prove just what organisms are primary and what others are secondary. A number of years ago at Barnard Hospital a number of us studied the bacterial flora of a number of ulcers and inflammations in which the etiology was known, such as tuberculous ulcers, cancerous ulcers, and some others. We were able to find all sorts of organisms, particularly staphylococci, streptococci and *Bacillus proteus*. The finding of these organisms of course showed only that in these particular instances they were present as secondary invaders. The purpose of this work was to show that the presence of such organisms did not prove that they were the cause of the disease. They are commonly found in any inflammation. Our group here published the results of our work in a number of papers on the role of *Pityrosporum ovale* in seborrheic dermatitis. Of course as yet we cannot say that it is proved beyond a fraction of a doubt that this organism produces seborrheic dermatitis. Our opinion is that it does. However, we all maintain an open mind on this subject.

DR. HAMILTON MONTGOMERY, Rochester, Minn.: Time did not permit Dr. Williams to discuss disturbance in lipoids in regard to so-called seborrheic dermatitis or to give detailed reports of the representative cases which are given in the substance of this paper. In regard to *Pityrosporum ovale* as an etiologic agent we used Difco wort agar according to the technic outlined by Moore in all thirty-four cases but in none of these were we able to obtain positive cultures. *Pityrosporum ovale* was present in two cases on direct examination. We found an aspergillus in one case. I have had the opportunity of seeing many of Dr. Mitchell's cases of streptococcal dermatitis which he has presented at the meetings of the Chicago Dermatological Society and at other meetings and in which he has been able to demonstrate the presence of streptococci not only from behind and within the ears but also from the scalp and various intertriginous folds, and which we used to call "seborrheic eczema of Unna." I appreciate that Dr. Mitchell isn't trying to make all these cases out to be streptococcal dermatitis and we have seen several cases which duplicated the clinical picture of his cases but in which only staphylococci could be demonstrated on culture. In one of these cases there subsequently developed a severe mastitis of the breast from which pure *Staphylococcus aureus* was grown in culture. In this case one should regard the staphylococcus as a definite etiologic factor. We had two women employees of the clinic in this group who had had infantile eczema and typical atopic eczema on which recently there was superimposed a severe retro-auricular weeping moist dermatitis involving the ear canal. This dermatitis did not respond to the usual types of treatment directed toward an atopic eczema but did respond promptly to the use of mercurial preparations and gentian violet such as one would employ in treating a streptococcal dermatitis. Furthermore, both streptococci and staphylococci were present in cultures from the affected areas. One cannot definitely state, however, that the streptococcus or staphylococcus or any other bacteria or fungi are the etiologic factors in a given case owing to the fact that as yet it has been impossible to fulfil Koch's postulate.

THE SYMPTOMATOLOGY OF LYMPHOMA

ITS ENDLESS VARIETY

J. H. MEANS, M.D.

BOSTON

Experience in the medical wards of a general hospital over a period of many years has indicated to me, as doubtless to many other physicians, that lymphoma is a disease both ubiquitous and pleomorphic, presenting itself in ever changing symptomatology. It has a great capacity for producing bizarre clinical pictures and a strong propensity for having its entry heralded by symptoms and signs diagnostically misleading. Again and again it is met at operating or autopsy table, previously unsuspected, yet unquestionably the cause of the clinical picture. I have nothing authoritative to say on lymphoma. I shall not even present statistics or discuss the literature. I merely wish to point out the importance of considering lymphoma in the differential diagnosis of obscure conditions and to discuss briefly the question: When, as practitioners obliged to make diagnoses, should we think of lymphoma?

On what is known of the nature of the disease we may dwell for a moment. Of its cause nothing definite is known, although the production of lymphomatous-like tissue in mice by benzene¹ and the finding of tissue resembling lymphoma² in man with benzene poisoning suggests a humoral origin of some sort. The disease is generally considered to be neoplastic—a neoplasm taking origin from a cell of the lymphocyte series anywhere between the primordial or stem cell and the mature cellular elements. Pathologists recognize several types described by such terms as lymphoblastoma,³ reticulum cell sarcoma, lymphosarcoma, Hodgkin's disease and giant follicular lymphoma. Whether these types represent separate entities or merely varieties of a single entity is undecided. That in certain cases the pathologic picture may pass from one type to another suggests that the disease is fundamentally unitary. As clinicians, we are more concerned with whether our patient has lymphoma or has not lymphoma than with what kind of lymphoma he has. All types are, relatively speaking, radiosensitive and yield to some extent for a time to rather low dosage of radiation. This fact, together with the added one that surgery, unless necessary to relieve some complication, is generally contraindicated, is the chief reason why correct diagnosis of the presence or absence of lymphoma is important.

The type of pathologic picture is of some interest to the clinician, in that it has been shown that rate of progress of the disease bears some relation to the anatomic picture. Thus Gall⁴ has shown that life expectancy is longer when the anatomic picture called giant follicular lymphoma is present than in any of the others. That type is seemingly the least malignant of the lot.

From the Medical Clinic of the Massachusetts General Hospital.
Read before the Section on Practice of Medicine at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

2. Mallory, T. B.; Gall, E. A., and Hunter, F. T.: Personal communication to the author.

3. This term has been used with at least two different meanings. It has sometimes been employed as an all inclusive term, synonymous with lymphoma, as used in the present paper. It also has been used to denote a tumor specifically derived from the cell in the stage of lymphoblast, in contrast, for example, to one derived from the lymphocyte, which might be called lymphocytoma.

4. Gall, E. A.: Personal communication to the author.

Although fundamentally neoplastic, the disease lymphoma resembles more closely in its clinical course and behavior certain chronic infections than it does other malignant tumors. While it may start locally in one particular lymph node or other tissue where cells of the lymphatic series are present, its inherent tendency is to become systemic or even constitutional. Moreover, in most cases at some stage of the disease the course is febrile. This perhaps is chiefly responsible for the similarity to an infectious process.

The symptoms of the disease may be the result of local interference with the function of involved organs or of pressure on neighboring ones, or of the general effects of the systemic extension of the lymphomatous process, such as fever, fatigue or itching. Since almost any part, or parts, of the body may be involved, the symptoms and signs which may be produced are nearly endless. It is my feeling that neither syphilis nor tuberculosis has anything on lymphoma in this respect.

The disease which most closely resembles it from the point of view of variety of picture and structures involved, as pointed out by Hunter,⁵ and from which it must be distinguished because of the great difference in prognosis, is Hutchinson-Boeck's disease, or generalized sarcoid.

Let me cite some case summaries and then attempt to answer my question. Of the classic type of onset with localized or general lymphadenopathy, with or without splenomegaly or hepatomegaly, I shall say nothing. It is with the less obvious symptom pictures that I am concerned. Let us begin with primarily gastrointestinal pictures. The following will indicate the variety:

CASE 1.—A man of 55 came in with the picture of acute small bowel obstruction. The symptoms were of but a few hours' duration at entry. He had previously been well. Laparotomy disclosed a perforated tumor about 6 cm. in diameter obstructing the small bowel about at its midportion. On removal, the pathologist called it a reticulum cell or Hodgkin's sarcoma. A year later the patient developed a slight generalized lymphadenopathy, yielding promptly to roentgen therapy but showing on biopsy a picture which the pathologist could not identify with certainty as lymphoma. Lymphoma was quite unsuspected prior to operation in this case.

CASE 2.—A man of 61 for three years had had symptoms quite characteristic of peptic ulcer, with one episode of perforation. Six months before entry he had developed enlargement of lymph nodes in axillae and groins, which had been diagnosed Hodgkin's disease at biopsy. Roentgen treatment had made his ulcer-like symptoms worse, and a month before entry he had had a gastrointestinal hemorrhage. At entry x-ray examination showed a deformity of the antrum of the stomach and duodenum of very unusual character, not at all like peptic ulcer. During roentgen treatment over the stomach area he had several more hemorrhages. At autopsy, two years later, a very widespread lymphomatous (Hodgkin's type) disease was found, with induration and ulceration involving the stomach, pylorus and duodenum. The esophagus was involved also in a similar process, the common bile duct was occluded by tumor and there was invasion of the spinal nerve roots and spinal ganglions and of the pericardium.

CASE 3.—A man of 52 presented a four and a half year history of alternating constipation and mild diarrhea with progressive weight loss, anorexia and asthenia. A fortnight before entry he had had a sudden massive hemorrhage by rectum, passing both bright blood and black stools and going into severe shock, from which he was revived at another hospital by several transfusions. Physical examination disclosed a pale, poorly nourished man with a slightly distended abdomen and a mass in the epigastrium which was thought to be the left

lobe of the liver. Neither the spleen nor any lymph nodes were palpable. The blood showed an impressive anemia with about normal color and volume index, and leukopenia. X-ray examination of the chest revealed multiple discrete areas of hazy density scattered throughout both lung fields. The hilus shadows were prominent on both sides and slightly lobulated. The radiologist considered the condition consistent with metastatic malignancy. Barium sulfate examination showed no sign of disease in the alimentary canal, but there was evidence of enlargement of the liver. The preliminary diagnoses were cancer of stomach or bowel with metastases to the liver or primary cancer of the gallbladder. Exploratory laparotomy was decided on and disclosed a large number of metastatic areas of malignant disease which looked like carcinoma. Several areas of annular thickening of the small bowel with superficial ulceration were found and the portion of the bowel bearing them excised. To every one's surprise a section taken from the liver proved on microscopic examination to be lymphoma of Hodgkin's type. The intestinal lesions also were anatomically consistent with the diagnosis. He survived the operation by only three days, so there was no opportunity to give radiation therapy. At autopsy it was found that the lymphomatous process involved lungs and adrenals as well as liver and intestine.

CASE 4.—A man of 54 previously had had an attack like acute appendicitis. Following this there developed persistent lower abdominal midline soreness, worse a half hour after eating and accompanied by constipation. Progressive anorexia, asthenia and weight loss also characterized the picture. At entry he was evidently sick. He had a slight general lymphadenopathy and palpable liver and spleen. He also had a sustained low grade fever. I made a diagnosis of probable lymphoma and Dr. C. M. Jones thought he also had small bowel obstruction and advised laparotomy. X-ray examination of the gastrointestinal tract, however, was negative and biopsy of a lymph node showed a lesion undoubtedly lymphomatous. There was some difference of opinion as between giant follicular lymphoma and Hodgkin's disease. He improved very rapidly on roentgen treatment, relapsed, improved again and now, two years later, is x-ray fast and failing rapidly. The symptom type represented can be described as that of cachexia with lower abdominal symptoms suggesting partial intestinal obstruction.

CASE 5.—A man of 52 came in with a four and a half month story of feeling of pressure under the xiphoid process and fullness after meals. Increasing constipation began at the same time. Four weeks before entry he began to have steady, non-radiating, severe epigastric pain, not relieved by food but relieved by vomiting. At this time a gastrointestinal series by a skillful radiologist was interpreted as duodenal ulcer. At entry, examination showed evidence of weight loss and tenderness, without spasm, on deep pressure in the epigastrium. X-ray examination showed thickened gastric rugae, interpreted as gastritis, spasticity of the antrum of the stomach and a deformed duodenal cap with an ulcer crater on the anterior wall at the lesser curvature. There was extreme tenderness to palpation in the region of the crater. A diagnosis of penetrating duodenal ulcer was made.

He was started off on a medical regimen for ulcer, but on this he did not improve and then gastric analysis disclosed that he had achlorhydria, a finding not consistent with peptic ulcer. A third x-ray examination, twelve days after the second, showed an unusual type of swelling of the inner surface of the prepyloric region and within the first and second portions of the duodenum. The adjacent loop of jejunum also showed swelling. The duodenal cap showed ulceration. The radiologist suggested that a lesion outside the duodenum and upper small intestine with secondary involvement of the intestine, or multiple areas of lymphoma, might explain the picture.

Laparotomy was decided on. It disclosed a large mass in the duodenum which seemed to be inflammatory thickening. To this the liver was adherent. The entire lesion had the appearance of an inflammatory ulcer which had penetrated through the anterior surface of the duodenum, perforation being prevented by adhesions. Behind the stomach, leading to the duodenum and extending up and down the vertebral column, was a diffuse retroperitoneal infiltration having all the char-

5. Hunter, F. T.: Hutchinson-Boeck's Disease (Generalized Sarcoidosis), *New England J. Med.* 214: 346, 1936.

acteristics of malignant disease, including involvement of regional lymph nodes. On biopsy these gave the picture of chronic inflammation, but the patient died a fortnight after operation and autopsy disclosed an ulcerating process involving the anterior wall of the duodenum which on microscopic examination showed the picture of lymphoma together with a marked inflammatory reaction presumably the result of subacute perforation.

In a considerable number of cases the presenting symptomatology is predominantly thoracic. Sometimes pulmonary tuberculosis or bronchogenic cancer are mimicked rather closely. For example:

CASE 6.—A man of 65 for nine months had had continuous dull ache in the left shoulder and left pectoral region, which had grown steadily worse. It had been accompanied by productive cough. For five months the sputum had frequently been bloody and on several occasions there had been profuse hemoptysis. Physical examination disclosed a stony hard immovable mass deep below the right clavicle and a discrete movable hard nodule to the left of the trachea. There was a prominence in the region of the manubrium sterni which was dull to percussion.

The admission diagnosis was malignant disease of the lungs with metastases to the cervical lymph nodes, but after examining him myself I noted "The bleeding involves the bronchial tree, but it is a queer picture for bronchogenic cancer. I suppose a lymphoma could involve the trachea and cause bleeding."

X-ray examination showed a rounded mass with fuzzy borders just above the arch of the aorta, nonpulsating and 4 cm. in diameter. The radiologist thought the lesion to be metastatic or cancer of the bronchus, dermoid or lymphoma. Biopsy of the cervical mass proved the process to be one of lymphoma, Hodgkin's type. On roentgen treatment both the mediastinal mass and the mass in the neck practically disappeared.

CASE 7.—A man of 54, two months before entry, developed a persistent cough productive of a small amount of whitish sputum. A little later he noted progressive asthenia and anorexia. His voice also became hoarse. On several occasions he had had drenching sweats. Ten days before entry, the other symptoms continuing, he developed the added ones of dyspnea and orthopnea.

He was found to have a persistent low-grade fever. His lungs were emphysematous and there were signs of fluid at the right base. The apexes of the lungs were clear; no rales were heard at any point. The only adenopathy found consisted in a few shotty nodules in the right side of the neck. The white count varied between 10,000 and 19,000 per cubic centimeter, and the eosinophils from 10 to 14 per cent. On right thoracentesis, 1,200 cc. of amber colored fluid was obtained, showing a specific gravity of 1.020, a predominating lymphocytic and monocytic sediment, and forming a pellicle on standing. No tubercle bacilli were found in the sputum.

X-ray examination showed a large lobulated mass of the anterior mediastinum on both sides extending downward from the clavicle about 15 cm. There was considerable difference of opinion as to what it might be, but since it rapidly decreased in size on lymphoma dosage of x-rays, there was little doubt of its being lymphomatous, although this was never established by anatomic examination.

This case represents a type of onset which could have been that of pulmonary tuberculosis or of some non-tuberculous pulmonary infection.

We have had several cases recently in which the presenting symptomatology is that of acute upper mediastinal pressure. For example:

CASE 8.—A man of 27 had been quite well until ten days before entry, when he began to have cough, dyspnea developing into very urgent stridor. On arrival at the hospital he was choking to death and died before anything could be done about it either surgically or by irradiation. Had a roentgenogram been taken at the onset of his symptoms the lobulated mediastinal tumor which he presented would have been found and roentgen treatment might have relieved him.

Another mode of onset is with ascites and dependent edema as the presenting manifestation:

CASE 9.—A man of 72 had had increasing swelling of his abdomen and legs for eighteen months, also dyspnea and intermittent fever. Physical examination showed ascites (which on tapping proved chylous⁶), big liver and spleen and edema of the legs. His adenopathy was minimal, a few shotty nodes in the neck, axillae and groins, yet biopsy of one of them disclosed giant follicular lymphoma. A case of this type might easily have been taken at first blush for cirrhosis of the liver.

Onsets resembling pyelitis and rheumatic fever have also been encountered. Concerning the latter, for example, we have:

CASE 10.—A boy of 12 had had frequent attacks of transient polyarthritic pain for seven months without swelling. He had lost weight and shown increased irritability. Four months before an enlarged thymus had been found and treated by x-rays.

At entry he was found to have palpable submaxillary lymph nodes and a few small nodes elsewhere. Neither the liver nor the spleen was palpable. He had an irregular fever. There was dulness along the left side of the dorsal spine.

By x-ray examination there were found a peculiar appearance to the transverse process of the fifth lumbar vertebra and an elongated soft tissue mass along the left lateral margin of the spine at the level of the eighth and ninth ribs. The interpretation was primary malignant tumor arising in the transverse process of the fifth lumbar vertebra with metastases to the lymph nodes of the dorsal spine. Biopsy of the bone tumor showed it to be lymphoma of Hodgkin's type. Roentgen treatment relieved his symptoms, but he died eighteen months later, autopsy showing lymphoma of Hodgkin's type with widespread bone involvement and involvement of the lymph nodes, liver, spleen, kidney and meninges.

Time will not permit me to give more case summaries. The list of bizarre onsets and pictures, however, is far from exhausted. The material includes cases in which the symptoms appear as purely neurologic, for example paraplegia due to a lymphomatous tumor impinging on the spinal cord. There are cases in which the first manifestations are dermatologic or the result of osseous involvement. In several cases the initial involvement has been in the thyroid, raising a differential diagnosis of chronic thyroiditis or cancer. In one instance the first involvement was of the prostate, with typical prostatic symptoms; in another there was an initial bilateral testicular involvement with an associated lesion in an ethmoid sinus; and in another the primary event was involvement of the parotid gland.

COMMENT

Thus the question When in differential diagnosis should the doctor think of lymphoma? can perhaps be answered by saying that, not only in the obvious conditions of lymph node enlargement or splenic or hepatic enlargement but also in the case of any acute or chronic symptoms referable to the gastrointestinal tract, the genito-urinary tract, the lungs and mediastinum, the abdomen and retroperitoneal regions, the osseous system, the central nervous system, the skin, or in that of any local swellings seemingly neoplastic or chronic inflammatory in nature, not provably due to something else, the possibility of lymphoma should be considered. Particularly is the likelihood of lymphoma enhanced when the picture in question is characterized, among other things, by sustained or intermittent fever. Indeed, nowadays experience indicates that, if mistakes are to be kept to a minimum, the differential diagnosis of obscure prolonged fever or recurring bouts of fever should include tuberculosis, brucellosis, infections of

6. Chylous ascites comes close to being pathognomonic of lymphoma.

the urinary tract and biliary tract, concealed suppuration, disseminated lupus, amebiasis and lymphoma.

Chronic obscure ill health, particularly increased fatigability, is also sufficient reason to think of lymphoma. Fatigability seems particularly an expression of an extensive, though very often concealed, lymphomatous involvement of vital organs. Its rapid relief under roentgen treatment justifies this conclusion as to its origin. Roentgen treatment could hardly have this effect on such symptoms when due to any other cause.

The gastrointestinal types of lymphoma have particularly interested me. It seems almost proper to say When is an ulcer not an ulcer? When it's a cancer or lymphoma. Anything a bit off color in a picture apparently due to peptic ulcer may properly arouse suspicion of lymphoma, atypicality in the roentgenograms, failure to respond to adequate ulcer treatment, and so on. Multiple ulcerations are particularly suggestive of lymphoma.

Lesions of the small bowel deserve special mention. The small bowel is not heir to a great variety of lesions and, when it can be shown to be organically diseased with or without obstruction, lymphoma should come to mind as a good possibility.

The ability of lymphoma to cause massive bleeding, hemoptysis, hematemesis or bleeding by rectum also must be appreciated.

The absolute diagnosis of lymphoma can be made only by biopsy. Whenever the disease is suspected, every effort should be made to find a lymph node or other lesion which can be removed and studied microscopically. It should be borne in mind, however, that only the positive biopsy is significant. A negative one does not exclude the existence of lymphoma in the patient. Repeatedly we get reports of chronic inflammation on lymph glands from patients later proved in other ways or by repeat biopsies to have lymphoma. Indeed, such a warning may properly be issued regarding biopsies in general.

The x-ray appearance of intrathoracic or gastrointestinal lesions, however, sometimes gives almost uncontrovertible evidence, and the rapid melting of a lesion under x-radiation leaves only a very small if any doubt as to its lymphomatous nature. Subsidence of fever under such treatment has a similar significance.

When biopsy is impossible and when the likelihood of lymphoma is definite, observance of the behavior of a lesion under low (lymphoma) dosage of x-rays, before exploratory surgery is resorted to, is desirable. Ordinarily, however, radiologists are correct in insisting on a biopsy before embarking on roentgen treatment.

CONCLUSION

I urge you to think of lymphoma, not only under the varied circumstances I have particularly mentioned, but also under numerous others. I wish you to realize that this condition, which is composed of six or more types, has an endless variety to its symptomatology.

ABSTRACT OF DISCUSSION

DR. RALPH A. KINSELLA, St. Louis: It seems curious that confusion in symptomatology should be emphasized as a feature of a disease. The situation may perhaps be approached first by picturing the structure of a lymph node, the lymphocytes, the stroma, in particular the reticulocytes, and secondly by realizing that one of these anatomic elements may be disseminated throughout the entire body along the reaches of the lymphatic system. We have then, on the one hand, a variety

of changes that may occur in any one of the elements of the lymph gland, and then a distribution of these changes in any part of the body, so that emphasis may be given to symptoms in the abdomen, symptoms in the thorax or elsewhere, as Dr. Means has outlined. So we have the various pathologic types and the curious confusion in symptomatology. It has been in recent years that pathologists have arranged the different types of disease in the lymphatic system. The clinician, while ultimately seeing some difference between the patient with lymphosarcoma and the patient with Hodgkin's disease, is still unable to make clinical diagnoses of such conditions as lymphadenosis and reticulocytoma and to distinguish between leukemia as a disease, leukemic phases which may accompany any of the elementary disturbances. Dr. Means has emphasized the shifting character that a given case may show, without diagnostic features on which any particular pathologic type can be recognized, so that, grouping all these diseases together, it is justifiable to refer to lymphoma as a clinical entity and leave for the pathologist the determination of the particular cell change that has taken place. I am interested in those cases in which circulating blood changes may take place, the cases in which at least temporary lymphocytic leukemia may occur. I should like to ask Dr. Means one question, as to whether in his experience this has been an important feature in any or several of various pathologic types.

DR. JAMES H. MEANS, Boston: As to Dr. Kinsella's question about leukemia, I think I will leave the classification of these things to the pathologist. I am not a pathologist. I think the consensus is that lymphatic leukemia belongs in this group and that one could have a lymphoma blood picture with lymphatic leukemia or without. Certainly physicians see such cases, and I think the remarks I have made apply to lymphoma in the more usual clinical sense.

THE INCIDENCE AND RESULTS OF TREATMENT OF SUBCLINICAL AMEBIASIS

FRANK H. CONNELL, PH.D.

AND

HARRY T. FRENCH, M.D.

HANOVER, N. H.

During the last twenty-five years, sizable segments of practically every population group in this country and abroad have been examined for intestinal parasites. As Faust and his colleagues¹ have pointed out, "it is practically impossible to compare data on the parasite rates based on different population groups, utilizing different technics of diagnosis, and evaluating results according to individual idiosyncrasies." Nevertheless, because of such surveys it is now known that *Endamoeba histolytica* can be demonstrated wherever man is found without regard for race, latitude or social position. Furthermore, though accurate comparisons are impossible, it has been established beyond question that variation in incidence occurs among geographic, age and economic groups.

Craig,² on the basis of such surveys, has estimated that between 5 and 10 per cent of the population of this country as a whole harbors *Endamoeba histolytica*. If it is important for medical men to appreciate the seriousness of the picture for the country as a whole, it is equally important that they know with some degree

From the Department of Pathology, Dartmouth Medical School, and the Hitchcock Hospital.

Read before the Section on Gastro-Enterology and Proctology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

1. Faust, E. C.; Hoffman, W. A.; Jones, C. A., and Janer, J. L.: A Survey of Intestinal Parasites in Endemic Schistosomiasis Areas in Puerto Rico, Puerto Rico J. Pub. Health & Trop. Med. 9: 447 (June) 1934.

2. Craig, C. F.: The Pathology of Amebiasis in Carriers, Am. J. Trop. Med. 12: 285 (July) 1932.

of accuracy the incidence of amebiasis in their own locality. If surveys have served a useful purpose in the past, there still remains for the future a real need for accurate local investigations of the civilian noninstitutional population. Without an accurate idea of the amount of amebiasis occurring in his practice a physician may, and often does, fail to consider the possibility of an amebic infection if he lives in a region in which the incidence is low. On the other hand, it leads to distrust if a clinical laboratory in such a locality is forced to report a long series of negative examinations to a man who expects an incidence of 10 per cent.

Until the Craig complement fixation test becomes more generally available or new tests are devised, it is unfortunate that contact between the patient and the clinical laboratory, which in the last analysis must make the diagnosis, should be so distinctly second hand. Dobell in 1917 wrote: "The errors committed by an examiner of little or no previous experience are such as I could not have believed possible if I had not actually encountered them; and in cases where the health of a patient is at stake, it is, I believe, almost better that no examination at all should be made than that it should be made by an incompetent and inexperienced person." A little more than a year ago, Kellogg and Scott³ reported that in California the laboratory diagnosis of amebiasis was in an unsatisfactory state because of universal lack of trained personnel for work of this type and that "this, together with an equally widespread lack of understanding and appreciation of the situation on the part of everybody concerned, is productive of such a high percentage of unreliable reports, and their blind acceptance, that the situation is worse by far than if no laboratory tests at all were made in many, perhaps most, cases." What Dobell said over twenty years ago is still true today. What is true of Europe and California is equally true of New Hampshire, and it would be strange indeed if other points could not be found between the Atlantic and the Pacific where similar conditions exist.

The whole fault does not lie, however, with the training of our technicians. No technician can demonstrate amebas which have disintegrated by the time the specimen reaches the laboratory. Not only should a thoroughly trained and experienced person conduct the search for amebas but such a person should supervise the collection and subsequent handling of all specimens. How many patients, student nurses or physicians, for that matter, are familiar enough with the biologic peculiarities of *Endamoeba histolytica* to collect a specimen intelligently? It is a well known pedagogic principle that students will do just about as much as is required of them. By wider application, is it not likely that if it were realized how much more one ought to require by way of training for technicians there would be no problem?

It may appear that we have been merely restating old truths, but that lack of confidence in the diagnosis of amebiasis is widespread may be illustrated by the fact that in our annual examination of Dartmouth freshmen for amebiasis it has been found expedient to make, before treating a student, two permanent slides in order that we may have proof of his infection.

There exists in and around Hanover a stable, rural, nonindustrial population living alongside a college population whose members are drawn not only from all

corners of the country but very largely from that stratum of the population which economically possesses a surplus over and above the demands of daily existence.

A selection of all the known local rural population from our records reveals that 205 of them have been referred to our laboratory during the past six years on the basis of gastrointestinal symptoms and not one has been found positive for *Endamoeba histolytica*; this in spite of the fact that examination of a single specimen has been the exception rather than the rule and that the method or methods used were adapted to the nature of the specimen.⁴

During that same period five faculty members returning from foreign travels and three other residents of the state, all suffering from diarrhea or dysentery, have been found positive. One of the latter returned from the Spanish-American War with severe attacks of diarrhea and dysentery which persisted at frequent but irregular intervals down to the time of treatment for acute amebic dysentery in October 1936.

Fecal examination of the entering class at Dartmouth was undertaken by one of us (Connell) five years ago and has been retained as a part of the routine physical examination administered at matriculation. Five years ago, on the heels of the Chicago epidemic, the role of the food handler in the transmission of amebiasis was not as well understood as at present. In fact, as McCoy put it, there was little choice, from the point of view of society, between a carrier of *Endamoeba histolytica* and a leper. With nearly 100 freshmen working as food handlers it seemed a worthy project, especially since, on the basis of the current surveys,⁵ one might expect an incidence of better than 5 per cent. The early finding of two carriers waiting on the same table in college commons did nothing to lessen this impression. Furthermore, since Hanover seems to lie in the midst of a parasitologic desert with minimum opportunity for reinfection and since all patients treated might be expected to be available for reexamination for four years, it was felt that valuable information could be gathered on the efficacy of treatment in a disease prone, according to all records, to relapse.

The results of our examinations are as follows: In 1934 and 1936, when comparable methods of diagnosis were used, i. e. two specimens per man were obtained and a smear stained with Heidenhain's iron hematoxylin made from each, a total of 1,351 men were examined and twenty-four found positive for *Endamoeba histolytica*, an incidence of almost 1.8 per cent.

In 1935 lack of trained assistants made the satisfactory completion of a survey impossible. Recently, however, forty-five members of this class, taking our course in parasitology, were examined by a variety of methods, including culture and the zinc sulfate centrifugal flotation method devised by Faust and his colleagues at Tulane University of Louisiana School of Medicine. Of this group ten were found positive for one or more species of amebas and three of these, or nearly 7 per cent, were infected with *Endamoeba histolytica*.

These samplings have been a voluntary spare time undertaking; therefore, as the burden of college duties

4. The following methods are used by our laboratory in such combinations as are dictated by the nature of the specimen: direct microscopic examination, with and without iodine; formerly the DeRivas, now the Faust zinc sulfate flotation by centrifugation, concentration technique; culture, using St. John's medium, and hematoxylin stained smears.

3. Kellogg, W. H., and Scott, E. A.: The Laboratory Diagnosis of Amebiasis, *Am. J. Pub. Health* 27: 813 (Aug.) 1937.

has varied, so have the methods used and the number of specimens examined per man been varied.

In 1937, with less time available, a slide was prepared as before but only one specimen was collected. In a class of 684 men five positive specimens were found. This year, 1938, a single specimen was again collected and the De Rivas concentration technic was used. The eighty-four men found positive for some species of ameba were later reexamined by the zinc sulfate method and five men in a class of 670 were shown to be positive for *Endamoeba histolytica*.

How to explain the drop in incidence from approximately 1.8 per cent for the years 1934 and 1936 to around 0.7 per cent for the years 1937 and 1938? While it might seem to confirm the observation of Spector,⁶ who noted that in Chicago the incidence of *Endamoeba histolytica* among clinic patients fell from a high of 42 per cent for May 1934 to 2.4 per cent for February 1937, the drop in incidence among our students is unquestionably more apparent than real and due to variation in method.

Even though we do not believe that our examinations, even in 1934 and 1936, revealed more than half the infections actually present, they did at least point out again what every one seems prone to forget—that no part of the country is free from amebiasis. With positives from such widely separated points as Phoenix, Ariz., and Boston, Montreal and New Orleans, with fifteen states represented, including all the North Atlantic states except Delaware, Rhode Island and Maine, no one can afford to ignore the possibility of amebiasis for patients with gastrointestinal symptoms.

Granted that comparisons are dangerous, it nevertheless seems obvious, when one views the records for our rural and student groups alongside those of Andrews and Paulson⁷ for Baltimore clinic patients and those of Meleney and his colleagues⁸ for rural Tennessee that, in the temperate parts of our country at least, the probability of acquiring an amebic infection depends more on how one lives than on where one lives.

With nearly all workers in this field agreed that no one can carry *Endamoeba histolytica* without harm, we are impressed by the casual way in which many physicians refer to carriers as "just cyst passers." Several workers⁹ have reported extensive lesions including liver abscess found at autopsy in persons who were known to have been without recognizable symptoms of amebic infection. The carrier state is, therefore, as Craig² makes clear, dangerous not only to society but to the individual. Not only may he at any time come down with amebic diarrhea or dysentery but, lacking such spectacular manifestations of the disease, may go on for years in a state of lowered efficiency without suspecting that there is anything wrong.

Only eight of the thirty-seven students found infected had ever felt bad enough to seek medical attention, and only three of these for diarrhea or dysentery. It did them little good, however, for none were ever examined for amebas and among the previous diagnoses which may be noted in their histories are chronic appen-

ditis, ulcerative colitis and low grade peritonitis. One man with a history of frequent and sometimes severe attacks of diarrhea and dysentery over a period of four years had been treated by a diet consisting of boiled milk and rice!

While most of the twenty-nine infected students who had never sought medical attention for relief of symptoms readily admitted to one or more symptoms suggestive of the carrier state, it is significant that not one of these men thought he had anything really wrong with him. Two men even professed to believe that diarrhea once or twice a week was perfectly normal.

These same men, within a few months after treatment, almost invariably insisted that they felt better, had more energy, engaged in more extracurricular activities and were able to prepare for their classes more easily. If such statements are founded in fact rather than wishful thinking, some reflection of such changes might be expected to appear in a man's scholastic record. While many marked reversals of form have occurred, we must conclude that a course of carbarsone is not the answer for every poor student in college.

Several papers¹⁰ have been published fairly recently which report the results of treatment for such large numbers of persons with amebiasis that it would seem hardly worth while to report so small a group as ours if it were not for the fact that none of the thirty-seven persons treated have had a relapse, even though the minimum post-treatment examination procedure has consisted of examination of no less than three consecutive stools at the termination of treatment and a twice yearly check-up of two or more specimens for as long as the patient remains available. For the group reported, twenty have already remained negative for more than three years.

Carbarsone has been used in conjunction with emetine ever since it became available, and but one of our earliest cases received any other form of medication. The procedure has, of course, been varied to a certain extent according to the severity of the symptoms, but both carriers and those suffering from the more acute manifestations of the disease have received identical treatment, for the first five days; i. e., emetine hydrochloride, one-half grain (0.03 Gm.), intramuscularly twice a day for five days and, simultaneously, carbarsone, 0.25 Gm., orally twice a day for the same period. For most patients, including all those treated by French, carbarsone has then been continued for five additional days at the same rate. In a few cases, after the first five days of treatment, a rest period of five days was observed, after which the initial treatment was repeated. In all cases, including three persons suffering from acute dysentery, it has been impossible to demonstrate amebas in the stool after the third day of treatment. All men have been kept under close observation during the period when they were receiving both emetine and carbarsone. Those with diarrhea or dysentery have been kept in bed. No toxic symptoms have been noted.

While apparent relapses within forty days are reported by Craig¹¹ in 81 per cent of 130 persons treated with emetine alone and while apparent relapses following the use of carbarsone alone are not uncommon,

mon (Hakansson¹⁰), it seems unlikely to us that the perfect results achieved in our small series should be ascribed entirely to either chance or the procedure followed but to a considerable degree it should be credited to lack of opportunity for reinfection.

Furthermore, though Craig¹¹ warns specifically against the use of emetine, except for control of severe diarrhea or dysentery, we feel that the marked degenerative changes noted by James¹² in *Endamoeba histolytica* in vivo following very small doses of emetine (from $\frac{1}{8}$ to 4 grains [0.01 to 0.26 Gm.]) should not be ignored and that emetine in small doses may well be retained in the treatment of carriers in conjunction with other drugs, as reported for those patients treated by French.

SUMMARY

1. In this study 2,750 male college students were examined for amebiasis.

2. All Atlantic states north of Virginia (except Maine, Rhode Island and Delaware) are represented in the group found positive for *Endamoeba histolytica*, and no section of the country is without representation.

3. Carbarsone in conjunction with emetine has been used in treatment with no toxic symptoms or relapses noted. Twenty of the men treated have remained negative for more than three years.

ABSTRACT OF DISCUSSION

DR. JAMES L. BORLAND, Jacksonville, Fla.: I am in accord with every statement made by the authors. Infection by this protozoon in most localities approaches the incidence of syphilis. There is a lack of emphasis placed on this subject in medical schools and institutions for training technicians. It is futile to preach about the disasters which may attend infection by the organism if there is only a handful of technicians capable of recognizing the protozoon. The physician's lack of training is manifested by the frequency with which he accepts reports from untrained technicians and his failure to question inconsistent reports, such as the discovery of cysts in diarrheal stools. The solution rests on the demand by medical communities for adequate training of both medical students and technicians. A large number of patients who harbor *Endamoeba histolytica* have few, if any symptoms. This raises the question of whether the demonstration of *Endamoeba histolytica* in the stool means that the bowel has been damaged. There is evidence that extensive ulceration of the bowel may occur without producing symptoms. Pathologic studies indicate that amebic infection always causes some damage. The chief argument against this is that there have been found in all protozoal surveys, including my recent investigation, a number of persons harboring the parasite but not showing ill health. Colonic disorder has been demonstrated in every patient I have encountered with amebic infection from whom I was able to obtain a complete history and of whom I was able to make a thorough gastrointestinal examination. I believe it is better to regard a carrier of *Endamoeba histolytica* as diseased until more positive evidence appears to show that a true carrier state is possible. I should like to emphasize the difficulty in establishing a negative diagnosis. Fifty-eight per cent of the infections may be missed if only a single stool examination is made. Even in the most competent hands a positive diagnosis has been made at times only after the investigator has made fifteen consecutive daily stool examinations.

DR. GEORGE B. LAKE, Chicago: In view of the difficulty of making a laboratory diagnosis in some cases of subclinical amebiasis, clinicians ought not to overlook the value of the therapeutic test, nor ought they to assume that patients did not have amebiasis if they are relieved by such tests. Many

of these patients do not have symptoms of dysentery or even diarrhea, and every practicing clinician has a number of patients who complain of obscure belly consciousness when it is difficult or impossible to demonstrate any adequate reasons for it. After a number of examinations of the stool by capable laboratory technicians have been found negative for amebas, one is justified in attempting the therapeutic test. There are patients who are sensitive to the arsenicals, but it is quite allowable after finding out something about that to try carbarsone. I have had success in several of these cases with the iodine-containing vioform given in doses of 40 grains (2.6 Gm.) a day for ten days. I have seen patients who remained clear of symptoms for periods of from six months to a year, and then the belly consciousness returned. Another course of vioform again relieved them. Perhaps they didn't need any more, though in some cases I have given three courses of this sort at intervals of six months or a year. I am well aware that such treatment not based on adequate and positive laboratory diagnosis may not be considered technically scientific, but I submit that it is good clinical practice.

DR. A. L. LEVIN, New Orleans: The incidence of amebiasis in the Southern states can be judged by an interesting episode during the trying period of 1918. During my service at the base hospital in Camp Beauregard, Alexandria, La., I made a survey of 5,000 troops for intestinal parasites. The men were from Arkansas, Mississippi and Louisiana. Among 5,000, sixty were found infested with amebas and quite a number of these had no clinical evidence. Regarding treatment, I give emetine in conjunction with other remedies, 1 grain (0.065 Gm.) hypodermically daily for six doses. One must watch carefully for emetine poisoning. The eradication of cysts in the course of treatment is of vital importance and this point should be stressed. Carbarsone, in my experience, does not always eradicate cysts. I use iodoxyquinoline sulfonic acid or diodoquin with very good results. In exceptional cases, large doses of bismuth subnitrate 1 or 2 drachms (from 4 to 8 cc.) three times a day, advocated by Deeks many years ago, is of value.

DR. WALTER L. PALMER, Chicago: I rise to raise a question with regard to the relative pathogenicity of different strains of *Endamoeba histolytica* with particular reference to the so-called small cyst race. I am aware that experimentally the small race of *Endamoeba histolytica* produces lesions. Certain facts were noted in the Chicago epidemic, however, which I think may be of significance. Dr. Bertha Kaplan, an expert parasitologist, found the small cyst forms of *Endamoeba histolytica* present in the stools first in December 1933. Prior to that we had had a high incidence of the large cyst race with many cases of active amebic dysentery. During the winter of 1933-1934 the incidence of these large cyst forms decreased and the incidence of the so-called small cyst forms increased. Then, after the summer of 1934, they gradually decreased again. Dr. Kaplan found that the small cysts grew out in culture in only 18 to 20 per cent of the cases, whereas the large cysts almost invariably grew. In the beginning we considered these small cysts of *Endamoeba histolytica* to be pathogenic, but as time went on a question arose in our minds as to whether that was true. Two years ago I went over the records of all small cyst cases. There was no definite, objective evidence of pathogenicity. Many proctoscopic examinations had been made but no ulceration had been found. There was no unexplained blood in the stool, nor had there been any evidence of hepatic abscess. I was also unable to satisfy myself that there were any symptoms attributable to the presence of the small cyst race of *Endamoeba histolytica*. It is only fair to say that some of my colleagues took the opposite view. Many of the cases were treated with vioform. Some were treated with emetine, some with various other drugs. Sometimes the cysts disappeared and the symptoms disappeared; sometimes the cysts persisted and the symptoms did not persist; sometimes the symptoms and the cysts persisted in spite of emetine and in spite of vioform. I have therefore grave doubt as to the identity of these small cysts or at least doubt as to their pathogenicity and clinical significance. They seem to me to behave differently from the large cysts. I should like to ask the authors if they took cultures of the positive stools, what percentage of them grew

12. James, W. M.: The Effects of Certain Drugs on the Pathogenic *Entamoeba* of the Human Intestine, *Am. J. Trop. Dis. & Prev. Med.* 1: 431 (Dec.) 1913.

out, and whether the cysts they observed they would classify as small cysts or as large cysts.

DR. FRANK H. CONNELL, Hanover, N. H.: The difficulty in culturing small races to which Dr. Palmer refers is a common experience. In St. John's medium, which we use as a matter of routine, perhaps a third of the small races fail to become established. As to pathogenicity of small races, Meleney and his colleagues have shown that strains vary in virulence and that the size of the cysts formed by any race of *Endamoeba histolytica* is not a safe criterion of pathogenicity. I feel that all carriers should be treated regardless of the size of the cysts passed.

TEMPERATURE FACTORS IN CANCER AND EMBRYONAL CELL GROWTH

LAWRENCE W. SMITH, M.D.

AND

TEMPLE FAY, M.D.

Professor and Head of the Department of Pathology and Professor
and Head of the Department of Neurology and Neurosurgery,
Respectively, Temple University School of Medicine

PHILADELPHIA

This paper presents clinical, pathologic and biologic evidence that "temperature" plays one of the most important parts in the activation of embryonic cell growth. Preliminary laboratory and clinical experiments continue to emphasize the importance of certain critical temperature levels in such embryonic cell activation. These studies have been submitted to careful analysis in certain directions. As far as we can determine, while the hyperpyretic state has been explored rather widely clinically, reports of little or no work have been published on the effect of reduced temperatures in disease, particularly in its application to the cancer problem. Our observations have opened up an entirely new vista and approach. We submit this material as factual data, in the hope of stimulating interest and provoking further investigation in a field as yet practically untouched.

After a study by one of us (Fay) of body surface temperatures, based on a neurologic dermatome plan, it was disclosed that temperature in the extremities might fall from 12 to 22 degrees below that normal for the mouth and that, whereas the segments of the trunk were fairly uniform in their temperature response, the segment in which the breast lies (fifth thoracic) was extremely variable and showed an increase in temperature from 0.5 to 3 degrees above the temperature of segments lying within 2 inches on each side. The pattern was so variable in women because of cyclic manifestations of the menses and the physiologic variabilities encountered in lactation and gestation that no reliable average could be obtained. Even in males, the tendency to show an increase in the fifth thoracic segment was remarkable (fig. 1).

The question arose as to whether this local increased temperature might in some way be related to the fact that carcinoma finds a favorable location in the breast segment whereas both primary and metastatic carcinomas are known to be extremely uncommon in the extremities below the elbows and knees, where the body temperature is at its lowest level.

Attention was called recently to the low incidence of tumors of the hands and feet by Coley and Higginbotham,¹ who reported the occurrence of only forty-

seven tumors involving the bones of the extremities in 1,211 cases of all forms of primary bone tumors. Of these, less than half (twenty-one) were malignant, and of these only two were metastatic. Similarly, Mason² noted that carcinomas of the hands and feet are equally uncommon—not more than 5 or 10 per cent of all squamous type epitheliomas—and are usually of low grade malignancy. Pack and Adair³ brought out the fact that melanoma is the only form of tumor occurring with any considerable frequency on the hands or feet, 103, or approximately 21 per cent, of a total of 477 melanomas observed in a twenty-one year period at the Memorial Hospital having been in these areas. Of these seventy-four were on the foot and twenty-nine on the hand, almost exactly the reverse of the carcinoma picture, in which the frequency is two or three times greater for the hands. Geschickter and Copeland⁴ emphasized the comparative infrequency with which skeletal metastases involve the extremities.

Dermatome cutaneous temperature readings were made by a very ingenious and accurate thermocouple apparatus devised by Henny,⁵ capable of recording within a few seconds surface and internal temperatures to within one tenth of a degree centigrade.

In July 1936 Fay⁵ decided to attempt to reduce the temperature locally in the area of carcinomatous growth to that of the extremities and observe the effect on the tumor cells by means of repeated biopsies. The first patient (C. L.) was suffering from intractable

Fig. 1.—Cutaneous surface temperatures of twenty-seven normal males adjusted to a room temperature of 75 F.

pain from massive pelvic extension of a cervical carcinoma. She had both a rectovaginal and a vesicovaginal fistula. Three grains (0.2 Gm.) of morphine a day were not sufficient to control the pain. The patient was transferred to the neurosurgical service for chordotomy for relief of the terminal stages of suffering. A hollow capsule connected with a continuous circulation of ice water was inserted deep in the vaginal mass and continuous refrigeration of the local area maintained by

constant circulation of water through an enclosed system at approximately 36 F. At the end of forty-eight hours the patient was pain free. The dose of morphine was reduced and its administration promptly discontinued. The second observation of interest was that within five days there had appeared a definite devascularization of the carcinomatous area with shrinkage in the gross fungating mass. Within three weeks evidence

Fig. 2.—Temperature factors in chick embryo growth.

of fibrous tissue repair around the rectovaginal and vesicovaginal fistulas appeared and biopsy showed a definite degeneration of the tumor cells locally. It is noteworthy that during this period a temperature as low as 36 F. caused local ulceration about the normal areas near the vaginal outlet. The temperature was then permitted to continue at 48 F., which was found to be compatible with survival of the normal tissues.

Five weeks of continuous refrigeration had been accompanied by improvement in appetite, gain in weight, freedom from pain and gross shrinkage of the tumor mass. The patient insisted on leaving the hospital and returning to her family duties. She remained in good health for four and a half months, after which there was

Fig. 3.—Chick embryo incubated at 90 F. for an initial period of seventy-two hours and subsequently at normal incubation temperature. Note stunting and malformation of skeletal development as well as complete ectopia cordis.

metastatic carcinomatous lesions was usually in the areas with higher temperatures, namely the lungs, the liver, the brain and the central, better vascularized areas of the skeleton. Studies of the temperature of the various viscera have been pursued since that time whenever opportunity presented during the course of

surgical exploration of the various body cavities, and the data which have been collected in this fashion have merely confirmed what might well have been anticipated. Thus the ordinary oral temperature of 98.6 F. merely represents a mean average of the various temperatures of the several parts of the body made possible chiefly by the efficiency and integrity of the blood supply.

The work of Huggins and Noonan⁶ may throw much light on the entire problem. These authors demonstrated that red bone marrow, present in the tail segments and metatarsal bones of newborn rats, normally disappeared from the extremities and the tail in approximately two weeks if the animals were exposed to environmental temperatures. If, however, the distal half of the rat's tail was implanted in the abdomen or back or the feet amputated and placed in the abdominal cavity, red bone marrow persisted during the long period of observation. The portion of the tail exposed to environmental temperatures, however, showed the

Fig. 4.—Instruments used in the refrigeration treatment of cancer of (a) the cervix uteri, (b) the intra-uterine fundus, (c) the breast (hollow blade for use under lesions) and (d) a stilet type of instrument for penetrating large tumor masses directly.

replacement of red bone marrow by yellow bone marrow, and it was concluded that the favorable temperature of the body was responsible for the retention in activity of red bone marrow. These observations were extended to other animals and to birds. Furthermore these authors found that, if young rats were raised in the environmental temperature of 95 F., red bone marrow persisted in the tail and small bones of the extremities.

As will be seen later from our observations, the important critical level of 95 F. apparently applies to the cavity of red bone marrow as it does to certain responses in the chick embryo and in carcinomatous cell growth. Another analogy might be permissible at this point, namely that red bone marrow represents the only normal metastatic type of cell proliferation which is continuously carried on in the body structure, and

6. Huggins, C., and Noonan, W. J.: An Increase in Reticulo-Endothelial Cells in Outlying Bone Marrow Consequent upon a Local Increase in Temperature, *J. Exper. Med.* 54: 275, 1936.

the tendency of carcinoma to metastasize into the blood stream may be worthy of consideration.

Our studies have concerned themselves not only with biopsy studies of patients subjected to local and general refrigeration for hopeless metastatic carcinoma but with careful analysis of the chick embryo and of certain plants through a wide range of temperature activity.

Fig. 5 (case 1).—Malignant melanoma of the vulva: Biopsy specimen taken before treatment, showing characteristic large polyhedral cells arranged in almost solid sheets, huge ovoid or round nuclei with prominent nucleoli and coarse chromatin granules and pale and granular cytoplasm. Note the typical melanin pigment visible both intracellularly and extracellularly, especially in the stroma.

Two common principles apparently apply to cellular activity, embryonal cell development and plant germination. Although the critical temperature bands may vary between flora and fauna, it seems possible for us to present tentatively the following two corollaries:

1. Favorable temperature is the chief activator in cell growth.
2. The physical spectrum (from x-rays to ultraviolet rays) contains some quality which is inhibitory to cellular growth and regulates maturation and differentiation.

We do not have time here to go in detail into the various methods by which these tentative biologic laws have been reached. Suffice it to say that confirmatory evidence has been obtained in several ways. In the first place it has been shown by one of us (Smith) that varying the temperature during the incubation and growth period of chick embryos is invariably followed by some alteration from the normal, in retarding development, in producing malformations and actual monsters or in disintegrating the embryonic tissue early in its effort to differentiate. This is well brought out by figure 2.

The initial experiments in this direction were designed with the simple incubation of fertile eggs at

temperatures ranging from 108 to 90 F. for the twenty-one day period usually necessary for the normal hatching of the chick. There is a narrow range which might be spoken of as the optimal zone, in which normal growth, differentiation and organization of the tissues take place, with the development of a normal chick. This is between 97 and 104 F., although with either the upper or the lower level there will be an appreciable diminution in the number of viable chicks. Above 105 F. the temperature is too great for the successful growth and differentiation of embryonic tissue, and at 108 F. the embryo rarely persists in recognizable form for more than from forty-eight to ninety-six hours before completely disintegrating. At the lower level there is a critical temperature lying at approximately 94 or 95 F., at which there will be marked retardation in the development of the embryo and a viable chick will only rarely develop. Hatching takes place within twenty-three to twenty-six days when it occurs, and the chick usually dies within the first few hours. In the great majority of instances it is unable to peck its way out of the shell without assistance. Below this level there is still further retardation in the rate of growth and development of the embryo, and at 90 F. there will be no viable chicks, even when incubation is prolonged to thirty-eight or forty days. Indeed, differentiation seems to stop after the first few days of

Fig. 6 (case 1).—Specimen taken after ninety-six hours of refrigeration at 50 F. from the margin of a subcutaneous tumor nodule, showing normal unaffected connective tissue cells of the corium. Note the marked degenerative changes in the tumor cells characterized by loss of nuclear detail, actual disintegration of nuclear and cellular membranes and intercellular diffusion of pigment granules.

development and, while the embryo may remain alive throughout the entire incubation period, it can be safely stated that aside from the retardation and stunting of growth there will be various developmental defects such as incomplete wing buds, malformations of the feet,

failure of the body cavities to close either anteriorly or posteriorly and, almost always, ectopia cordis.

Subsequently, experiments were carried out in which the time interval during which these abnormal temperature levels were maintained was varied. It was found that the first forty-eight to seventy-two hours was the critical period, as eggs which were incubated at the

not as seriously detrimental as is the maintenance of a temperature just below the critical level and this would seem to be borne out by Coghill's comment that, aside from retardation of growth, nothing abnormal was noted in his embryos until after this variation in temperature had taken place.

In the attempt to demonstrate the importance of temperature with respect to embryonic cell growth, a second series of experiments was undertaken, in which the effect of temperature on the growth of normal and cancer cells was studied by tissue culture methods. This work is not sufficiently advanced for us to attempt to report it in detail, but preliminary observations bear out the theory that critical levels exist for these cells and that tumor cells are more readily affected by alteration in temperature than are normal, differentiated, adult type cells. For a third demonstration, one needs only to turn to a broad consideration of plant life to realize the importance of heat and light with respect to germination, growth, differentiation and organization of these structures. Experimental data in this connection are submitted as visual evidence confirming our hypothesis. It seems reasonable to state that the effects of temperature and light are universal physical laws which apply to all growing cells.

By logical sequence, the investigation of the effect of alteration in temperature on the growth of immature,

Fig. 7 (case 2).—Medullary carcinoma of the breast: Biopsy specimen taken before treatment, showing a typical highly malignant invasive medullary carcinoma without any suggestion of acinar formation. The cells show marked pleomorphism and anaplasia, with many atypical mitoses. There is a striking absence of desmoplastic stromal reaction.

critical level, between 90 and 93 F., for this brief period and then subsequently incubated at 103 F. for the remainder of the twenty-one day normal incubation time likewise showed 100 per cent of developmental defects (fig. 3), even to the extent of double-headed embryo formation.

Coghill⁷ further confirmed these observations regarding the effect of reduced temperatures on the development of embryos. He reported essentially the same results in the development of the embryos of *Amblystoma punctatum* Cope as the result of an accidental experiment in which the embryos were stored in an electrical refrigerator for a prolonged period and subjected inadvertently to what might well represent the critical level of incubation temperature for amblystoma by the accidental turning off of the current (defrosting), permitting a brief period of incubation. Later, when the clutch of amblystoma eggs was taken to his laboratory for hatching, the entire 138 embryos showed some form of developmental defect comparable to the malformations found in our chick embryos.

It is our impression, gained from additional chick experiments, that a temperature just above freezing is

Fig. 8 (case 2).—Specimen taken after one month's refrigeration at 50 F., showing several rather startling changes. Grossly the tumor had diminished in size by more than 80 per cent. Microscopic examination showed degeneration and disappearance of most of the tumor cells. There was marked reparative fibrosis, which in turn showed myxomatous features. Note also the vascular degeneration.

undifferentiated neoplastic cancer cells in human beings was the next step. Several patients with cancer that was inoperable because of widespread extension of the initial lesion either locally or by metastasis, some of whom had received the maximum amount of irradiation

7. Coghill, G. E.: Effects of Chilling on Structure and Behavior of Embryos of *Amblystoma Punctatum* Cope, Proc. Soc. Exper. Biol. & Med. 35: 71-74, 1936.

or had strikingly radioresistant cancers, volunteered for local refrigeration of the primary tumor mass. Thirty-eight patients with cancer of this type have now been treated by local refrigeration alone combined with artificial "hibernation," in which for periods as long as five days the body temperature as read by rectal thermocouple was maintained at levels as low as 85 or 90 F.

Fig. 9 (case 3).—Medullary carcinoma of the breast: Biopsy specimen taken before treatment, showing a rapidly growing carcinoma with undifferentiated tumor cells arranged in cords and clumps or singly, in purposeless fashion. The cell nuclei are large in comparison with the amount of cytoplasm. There is relatively little connective tissue stroma.

By refrigeration is meant the application of cold locally by means of ice water or a brine solution circulated through an apparatus designed especially to fit the structures in which the lesion exists and to secure the maximum distribution of the cooling process. By hibernation is meant a general reduction of body temperature below the critical level of 95 F. The necessary apparatus is designed by one of us (Fay) to meet the requirements of the individual patient (fig. 4).

The clinical and local results of refrigeration were so startling and significant that further advantage appeared possible by a reduction of the body temperature as a whole to levels critical for embryonic cells. Thus artificial "hibernation" was induced through the withholding of food, complete exposure of the body to a constant low environmental temperature (50 to 60 F.), preferably maintained by an air conditioning unit, and light narcosis produced with small doses of avertin with amylene hydrate and of barbiturates. In addition the cold applied locally to the lesion and ice bags applied to the head and other parts of the body aid in the general reduction of temperature. A state of artificial "hibernation" can thus be maintained in which metabolism is reduced to an almost negligible figure, with arrest of bowel and renal function, and dur-

ing such hibernation neoplastic lesions are diminished in size even more strikingly than by refrigeration alone. Indeed, several patients with cerebral metastasis and resultant symptoms referable to the central nervous system on emergence from the hibernating stage have shown improvement in mental activity and sense of well being.

Clinically, certain striking results have been observed. In every instance there has been a prompt reduction in pain, which in most instances might be called complete local relief of pain. This is of particular interest because the majority of the patients had been receiving doses of sedatives as large as 5 or 6 grains (0.32 or 0.36 Gm.) of morphine a day and several had been referred to Dr. Fay's neurosurgical service for chordotomy for relief of pain. By the use of refrigeration it was possible to avoid surgical intervention and to eliminate sedation in almost every instance. This alone warrants further investigation of this method of treatment as an adjunct in the care of patients with cancer.

Furthermore, there has been regularly a rapid, gross, measurable decrease in the size of the lesion within twenty-four to forty-eight hours. In a few cases this has been as much as 50 per cent. This decrease in size has progressed steadily during the course of treatment.

Fig. 10 (case 3).—Specimen taken after ten days' refrigeration at 50 F., showing striking degenerative changes. Note the pyknosis and karyorrhexis of cells, the loss of all nuclear detail, the disintegration of cytoplasm and the granular and myxomatous necrosis of collagenous stroma. The lesion was grossly less than 50 per cent of its original size at this time.

There has been also a general improvement in the patient's condition, with a gain in weight, a better appetite and a change for the better in the mental state. There has regularly developed a notable tendency toward healing of previously intractable ulcerative cutaneous lesions and fistulous tracts. It must be remembered

that these patients had all been given up from the standpoint of the more orthodox methods: operation and irradiation.

There has been a marked retardation in recurrences, and the rate of growth during recurrences has been definitely diminished, as shown by careful studies by one of us (Smith) of serial biopsy specimens taken at intervals during the course of treatment. In at least

Fig. 11 (case 4).—Carcinoma simplex of the breast: Original biopsy specimen, presenting the characteristic picture of a diffuse carcinoma with many large sheets of relatively undifferentiated cells, showing considerable variation in the size of the nuclei, prominent nucleoli and occasional mitotic figures. The desmoplastic stromal response is fairly generous in places.

two instances there has been complete disappearance of the local lesion. Both of the patients happened to be relatively young persons, in their thirties, with cancer of the breast. One had a definitely scirrhous type of lesion associated with widespread skeletal metastasis and blindness, the result of metastatic tumor growth around the optic nerves and into the fundus. The other had a huge medullary ulcerative lesion, with extensive involvement of the local lymph nodes, a "frozen neck" and skeletal and cerebral metastases. The first patient remained free from tumor for more than two years. The metastatic bony lesions disappeared, and her sight returned to a point where she was capable of reading large type. The local lesion of the second patient disappeared and she has remained grossly free from recurrence for more than a year and a half. The metastatic skeletal lesions show repair by osteogenesis and the cerebral manifestations are greatly alleviated, although it is still too soon to know whether any permanent relief may be hoped for.

Our particular object in this paper is to present a few illustrative cases in which serial biopsy specimens were taken at varying intervals after the initiation of local refrigeration therapy (figs. 5-12). In general

it may be stated that an almost inevitable sequence of events takes place. Within the first twenty-four to forty-eight hours, as has already been stated, there is a measurable decrease in the size of the lesion. When the lesion is viewed under the microscope, this decrease appears to be due largely to a reduction in the blood supply as a result of what must be interpreted as persistent ischemia, the effect of continuous cold. When the specimen is compared with the pretherapy specimen, it is often difficult to recognize blood vessels except when they are of fair size, because of their constriction and the absence of red cells within their lumens. Similarly, there is in many instances associated edema of the tissues, which likewise seems to disappear, as suggested by the density with which the stromal collagen is packed.

At the time of the preliminary observation, it is doubtful whether one would lay undue emphasis on any changes in the tumor cells themselves were it not for the fact that, as a result of subsequent serial studies, early regressive phenomena may be recognized. Even within the first forty-eight hours we not infrequently find definite changes in the staining capacity of the tumor cells. These suggest cells which are not well fixed, with a certain amount of swelling and granular change affecting the cytoplasm and a slight loss of nuclear detail and brilliance with respect to the chromatin and nucleolar material. No significant degeneration

Fig. 12 (case 4).—Specimen taken after twenty-eight days' refrigeration at 50 F., showing the degenerative phenomena regularly encountered in such refrigerated lesions. The scirrhous areas had been somewhat refractory and a few persistent tumor cells could still be identified. Note many which show complete disintegration.

or necrosis seems to have occurred, and such changes as are present might well be interpreted as the result of inadequate nutrition due to the diminished blood supply, mild regressive phenomena which would be reversible if the blood supply were to become adequate again.

However, within the next few days there is no question as to whether or not anything has happened to the tumor cells. There is a degenerative picture which ranges from the minimal changes already noted to frank necrosis and complete disintegration of the cells. It is of interest and perhaps of significance that the more marked changes are usually seen in the deeper portions of the tumor, while the degeneration does not affect the better vascularized peripheral growing zone as promptly. This too is perhaps due to the blood supply. So long as the temperature locally is not reduced below an arbitrary figure of 40 F. no demonstrable changes take place in the overlying normal adult differentiated structures such as the skin and subcutaneous tissue. The rate of growth is materially reduced, as evidenced by a marked diminution in the number of mitotic figures and by the character of the cells, which in general fail to show the marked anaplasia of the pretherapy specimen. Accompanying the necrosis there is usually a prominent polynuclear cellular infiltration. Ultimately actual liquefaction and absorption take place, with disappearance of the necrotic tumor tissue.

On the basis of these clinical and microscopic observations, confirmed to a large extent experimentally through tissue culture methods, based on the hypothesis that temperature is important in the growth and differentiation of embryonic, young, undifferentiated cells, we suggest a wider investigation of this method of treatment as an adjunct to the methods in use today. We wish to emphasize the fact that this method represents merely another physical form of therapy, which is not recommended as curative in any sense of the word but is based on the premise that malignant tumor cells, representing immature, undifferentiated cells, are more susceptible to such physical agents as x-rays, radon and alteration in temperature than normal tissue. With this premise in mind, we believe that the maintenance of a temperature which is critical with respect to the capacity for growth and differentiation of such immature cells may influence them materially and that refrigeration therapy should be added to the armamentarium for the treatment of cancer.

In our investigations in this new field of research we have been encouraged by the fact that we are dealing with a tangible and measurable physical form of energy (heat), which can be controlled and regulated to any desired degree. The profound effect on growth which this one factor has exhibited is astonishing, on the one hand, now that we have observed its possibilities, but seems quite simple and obvious, on the other, when viewed from the standpoint of response in the biologic life about us and the well known agricultural dependence on the changes of the season. Further analysis of this physical factor shows it to be in the same physical spectrum as visual light, x-rays and radium. Nearer the center of the physical spectrum

lies a zone of transmutation of energy into heat (infrared) which is apparently concerned chiefly with activation and stimulation of embryonic cell growth. Far down in the same spectrum lies an inhibitory and destructive area known to science, extending from the ultraviolet to the gamma rays of radium. It would appear that optimal cellular activity and growth maturity arise from the proper interplay between the stimulative portion of the physical spectrum (critical heat zone) and the inhibitory and destructive zone arising just beyond the visual light band and extending to the bands of radium and x-rays.

When these facts are reduced to a mathematical concept (fig. 13) it would appear that the maximum destructive effect on embryonic cell activity could be produced by subtraction of the activating agent (heat) through methods of refrigeration and by intensification and selective use of the inhibitory and destructive portions of the spectrum (x-rays, radium and certain ultraviolet rays), so that an appropriate combination might

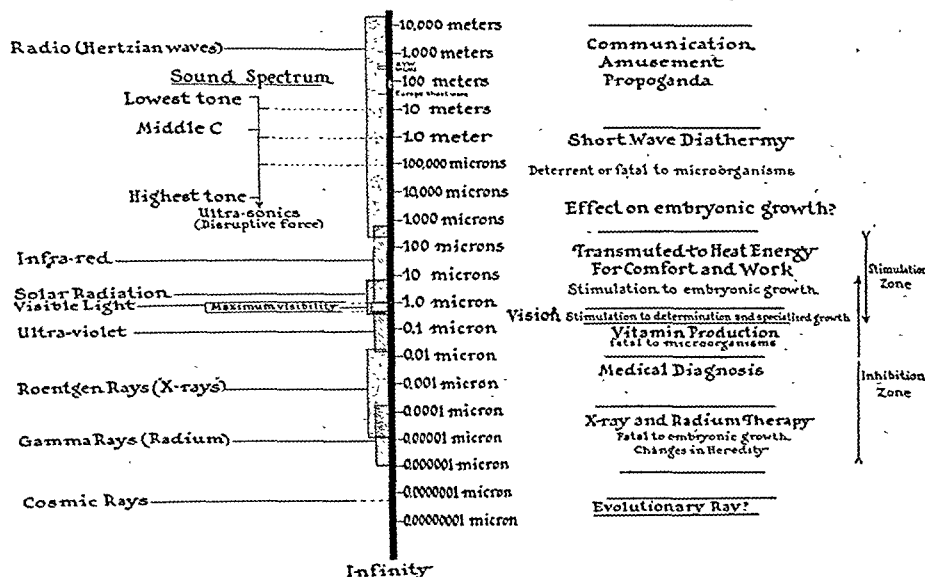

Fig. 13.—Physical spectrum.

conceivably be obtained to produce selective inhibitory and destructive effects in tissue beyond our present physical possibilities and the apparatus so far perfected. We are now conducting studies, to be reported later, on the effect of selective ultraviolet rays plus refrigeration.

SUMMARY

Relatively low body surface temperatures normally exist in the segments concerned with the extremities (from 88 to 90 F.), and the breast segment (fifth thoracic) tends to maintain a higher surface temperature than the adjacent segments of the trunk. There is relative infrequency of primary or metastatic carcinoma developing in those parts of the body enjoying reduced temperatures, as compared to the organs and portions of the body where optimal high temperatures are found.

Certain clinical, pathologic and biologic evidence indicates that young, undifferentiated cell growth and activity require an optimal temperature and that "critical" temperature levels exist below which these cells become inactive or undergo degenerative changes.

Local and general measures of "refrigeration" applied to patients suffering from hopeless metastatic carcinoma

have been discussed and the effects of these reduced temperatures on cell growth and activity, shown by serial biopsy and tissue cultures, indicated.

A "critical" level of around 95 F. has been noted below which undifferentiated cell growth, as exemplified by carcinoma pathologically and by the development of chick embryos, normally is arrested. Marked degenerative changes have been noted after seventy-two hours in biopsy specimens from carcinomatous tissues when continuously subjected to temperatures of 90 F. or below. Our observations have shown that normal cellular tissue is capable of withstanding 40 F. for prolonged periods of time without evidence of degenerative changes and normal reparative processes in carcinomatous areas maintained at this level. Tissue culture studies have confirmed these clinical observations.

Relief of pain encountered in terminal states of metastatic carcinoma has promptly followed "refrigeration" of the area involved or induced states of "hibernation" in which the patient has been maintained at levels of rectal temperature between 81 and 90 F. for periods as long as from one to five days.

Our observations suggest that the application of subcritical temperatures, through methods of local and general "refrigeration," may offer a valuable therapeutic adjunct to our present method of treatment of undifferentiated cell growth, particularly of carcinoma. Its practical clinical value and possibilities must await wider experience and more extensive and intensive observations.

ABSTRACT OF DISCUSSION

DR. TEMPLE S. FAY, Philadelphia: It may be of interest to know how we originally conceived the idea. Quite accidentally, in attempting to obtain a dermatome chart of body surface temperature, I came across the fact that the peripheral temperature in the normal subject lay well below this critical level of 95 F., whereas those areas in the breast segment might vary. After taking thermocouple readings of the uterus, brain and other parts, we found them to be around 100 degrees, which was the optimum not only for the undifferentiated embryonal but also for the carcinoma cell. It occurred to me that if we could maintain the entire body temperature at the level of the periphery (the Geschickter chart indicating the rarity of metastatic lesions below the elbows and knees) we might influence metastatic areas in the body as a whole. Therefore, in bringing out what Dr. Smith has so definitely substantiated pathologically (original observations were presented before the American College of Surgeons, a year and a half ago, *Surg., Gynec. & Obst.* February 1938), the embryology as well as the tissue culture studies have indicated that we are dealing with a more important phenomenon, perhaps, than that just concerning carcinoma and embryonal cell activity, a physical principle that biologically concerns the entire field of cell activity and growth. I have but little to add to the paper excepting to say that in this field so far we have not attempted to promote or produce a means of treatment. We have attempted only to analyze the effect of temperature on certain undifferentiated embryonal cells. I may say to those who may attempt to use this refrigeration method that each case is its own definite problem. We have had to construct our own apparatus to fit each individual. It is most important to maintain careful thermocouple readings of the tissue temperatures in order to establish whether or not one has reached the level of refrigeration that one desires. Clinically we find that this reduction in temperature relieves pain, thus saving the individual from neurosurgical operative procedures. It is also possible to relieve the patient of narcosis.

DR. ISRAEL DAVIDSOHN, Chicago: I wanted to ask Dr. Smith whether he is familiar with observations on malignant tumors in coldblooded animals, which might possibly throw some light on these very interesting phenomena.

DR. MARY B. BAUGHMAN, Richmond, Va.: I have a number of women with carcinoma at the menopause, and I have found that I can get some relief from pain by the injection of ovarian hormones to stabilize their general condition. I wonder whether that would not have somewhat of a tendency to lower the temperature, the pelvic temperature.

DR. F. W. HARTMAN, Detroit: I should like to ask what relation, if any, this work may have to the effect of higher temperature on embryonic growth, tumors particularly. Warren of Rochester, of course, has tried fever therapy in various types of malignant disease, with limited success. I have seen a few cases in Detroit treated with fever therapy alone or with combinations of fever therapy and irradiation. Some of these cases have responded very nicely. We have at least one bone sarcoma of the clavicle now well seven years, after a combination treatment of this kind. There may be a definite possibility of combining the refrigeration with the fever therapy. Switching from one to the other, perhaps, would kill these few remaining cells which apparently are the difficult ones to eradicate, whether one uses x-rays or fever or, in this case, refrigeration.

DR. LAWRENCE W. SMITH, Philadelphia: In reply to Dr. Davidsohn's question, yes, we have discussed this at great length with Dr. Lucké and others who have been working in the tumor field with cold-blooded animals. I think the temperature factor still exists as a major biologic principle but that the critical levels for different forms of animal life may vary. Assuming that the safe differential levels in temperature exist, I think one will find it just as applicable in the cold-blooded group as in the warm-blooded group. As far as Dr. Baughman's question goes, this is not an attempt to correlate any of the other extremely valuable work in the endocrine treatment of cancer. We wish to emphasize that treatment has not been a major premise in this work at all. It has only been an experimental observation of the effect of temperature on embryonal cell growth. Dr. Hartman's question is very timely. There are several things which I can think of in answer to the points which he brings up. First, arguing a priori, if fever therapy is used, one must put the cells, on the way up at least, through the growth stimulating zone. In the second place, we know from a good many and some rather serious results that fever therapy is not without its dangers. There have been a number of cases in which death has occurred as a result of such therapy. We know that certain permanent changes in the central nervous system may occur when the temperature gets up into the vicinity of 107 or 108 F. In other words, there is in fever therapy a very narrow temperature range in which tumor cells may be destroyed without, at the same time, destroying normal tissue. In refrigeration therapy there is apparently an almost limitless differential in the temperature field in that normal cells, as far as we can determine from all the experimental evidence at hand to date, are not affected by temperatures as low as 40 F., whereas tumor cells begin to show these changes at levels a little below 95, so that we have a differential factor of safety of nearly 50 degrees in temperature as against perhaps half a degree or so on the fever side. If one thinks of this in terms of therapeutics at all, I believe we have at most merely an adjunct to therapy of cancer by other methods. We hope that a combination of these methods may be very important in the future. If we start our cases out with refrigeration therapy and hit them at these temperature levels where cell growth is not going to occur, where we can at least put them into a stage, so to speak, of inactivity, and then perhaps bombard them with x-rays or radium or other method of treatment, we may have something which may be important. At the moment we have a means of treating intractable cancer in its last stages and providing comparative comfort for these patients, because their pain is practically eliminated. Healing is stimulated and we have gotten rid of foul smelling, sloughing, ulcerative lesions in some of these cases. From the standpoint of application of this treatment, the control of pain is the outstanding part of the story.

FAMILIAL NEPHRITIS

REPORT OF CASES AND REVIEW OF
THE LITERATURE

SOLOMON S. RINKOFF, M.D.

ABNER STERN, M.D.

AND

HENRY SCHUMER, M.D.

NEW YORK

It has been known for a long time that certain disease entities have familial tendencies. Some examples of this are hemophilia, allergy, acholuric jaundice, insanity, diabetes and general arteriosclerosis and hypertension. With the exception of postscarlatinal nephritis, however, there are comparatively few recorded instances of chronic diffuse glomerular nephritis in two or more members of the same family.

Dickinson¹ reported a family in which for three generations many members had albuminuria.

Pel² studied the genealogical tree of a family for three generations in which there were nineteen cases of nephritis which seemed to be of a chronic interstitial type. Several of these nineteen patients died with uremia. Males and females were equally affected. All the sufferers passed the disease to the next generation with the exception of one daughter, who had six children all free from nephritis. The progeny of the non-sufferers were free from the disease.

Meigs³ reported a family in which the father suffered from nephritis; three of his children, two daughters and one son, died of nephritis and another daughter was afflicted with the disease.

Kidd⁴ reported his observations of the incidence of nephritis in a family studied for three generations. In the second generation seven died of kidney disease and two others suffered with it. Three members of the family were free from the disease. The two children noted in the third generation also had nephritis.

Thomson and Macauley⁵ reported four cases of nephritis in one family following influenza.

Benson⁶ reported a family in which nephritis successively developed in four children. Three died at intervals of about a year.

Eason and his associates⁷ reviewed the reports of familial nephritis in the literature and added three more instances. In the first family there was a marked association of apoplexy and nephritis, six members being affected by one or both diseases. In another family there were seven cases of nephritis, five of which were discovered in childhood and adolescence. Four of these were diagnosed within a few weeks of one another. In the third instance three brothers aged 18, 19 and 20 years respectively and one sister aged 10 years developed nephritis within a period of two months.

Ernstene and his associates⁸ reported a familial outbreak of acute diffuse glomerulonephritis. Eight of ten children successively developed sore throat, fever,

coryza, headache and general malaise, which lasted for a period of from three to seven days. (No child showed any evidence of scarlatina, but three had had scarlatina three years previously). In six of these children, signs and symptoms of acute diffuse glomerulonephritis developed during convalescence from seven to twelve days after the onset of infection. Absolute proof of the identity of the organism causing the infection could not be determined, although cultures of material from the throat yielded streptococci. All the children recovered within eighteen months.

REPORT OF CASES

Our instance of familial nephritis occurred in three brothers aged 24, 25 and 23. All of them died after a

Fig. 1 (case 3).—Section showing thickening of Bowman's capsule (arrow), complete replacement of glomerular tuft by scar tissues and cystic tubules filled with hyaline material.

comparatively short period of renal insufficiency terminating in uremia and death.

CASE 1.—G. B., aged 24, a grocer, was admitted to the Mount Sinai Hospital March 17, 1931, and died March 24. He gave a history of frequent sore throats and colds. Six months prior to his admission he contracted scabies. About this time he began to complain of weakness, crops of boils and loss of weight. Three weeks prior to admission nosebleeds, insomnia, nervousness, palpitation and diminution of urinary output developed. Faintness and vomiting appeared during the three days prior to admission.

On physical examination the patient was acutely ill with flushed face, rapid deep respiration and distinctly urinous breath. The fundi showed pallor of the disks, extremely narrow arteries and perivascularitis and a few exudates. The blood pressure on admission was 150 systolic, 100 diastolic. Later it dropped to 116 systolic, 76 diastolic and finally was recorded

Acknowledgment is made to Dr. Joseph Felsen, director of pathology, for the photomicrographs and pathologic studies and to Dr. Gamiel Saland, chief of the peripheral vascular department of the Bronx Hospital for his aid in the clinical studies.

as 150 systolic, 96 diastolic. Examination of the blood revealed a hemoglobin content of 70 per cent and 20,100 white blood cells with 84 per cent polymorphonuclear leukocytes. The blood urea was 260 mg. per hundred cubic centimeters, the blood calcium was 5.7 mg. per hundred cubic centimeters and the carbon dioxide combining power 14.3 volumes per cent. The urine showed a trace of albumin, rare casts and occasional white blood cells; the guaiac test gave negative results. (The concentration test was not done because of the uremia.)

During his stay in the hospital the patient had a few brief epistaxes, and despite the forcing of fluids parenterally there was only a slight drop in the blood urea and rise of the carbon dioxide combining power. He went steadily downhill, the vomiting increasing progressively, and he died a week after admission.

Fig. 2 (case 1).—Section showing marked thickening of Bowman's capsule and adherent glomerular tuft. Compare with similar structure indicated by arrow in figure 1. (Slide obtained through the courtesy of Dr. Paul Klemperer, Mount Sinai Hospital.)

NECROPSY

Necropsy was performed by Drs. Arthur Schifrin and David Beres.

Gross Pathologic Changes.—These consisted of chronic glomerulonephritis with secondary contracted kidneys; acute fibrinous pericarditis (marked); hypertrophy of the left ventricle (moderate); hemorrhagic gastritis and jejunitis (uremic); chronic passive congestion of the spleen; bilateral pleural effusion and pulmonary edema; hemosiderosis of the liver, spleen (and lung?); bilateral dilatation of calices and ureters (mild); multiple cysts of the kidneys, pinhead to 6 mm. in size (due to fibrosis), and granular deposits on the liver, spleen and pleura—nature (?).

Histopathologic Changes.—There was marked atrophy at the surface of the kidney. The raised areas corresponded to underlying dilated and enlarged tubules; the depressed areas to zones of increased dense connective tissue in which numerous completely and partly hyalinized and shrunken glomeruli were present. The glomeruli were diffusely involved. In the atrophic areas they were as described. Many gradations were seen

with adhesions to Bowman's capsule, thickening and fusion of loops. Crescents as such were not seen. In some places there was marked extracapsular thickening. There were still quite a few glomeruli which under low power appeared normal but under high power showed fusion of loops. In these blood might, however, still be seen.

Tubules were collapsed and replaced by connective tissue in atrophic areas. Dilated tubules contained no blood.

Interstitial tissue was fibrotic with many foci of darkly nucleated round cells. Large blood vessels showed congestion. Elastica stain showed only slight arteriolar sclerosis.

CASE 2.—M. B., a man aged 25, a hospital attendant at the Morrisania City Hospital, was admitted to the wards of that hospital July 30, 1934. His chief complaints were vomiting, abdominal pain, diarrhea, weakness, headache and nosebleeds.

One brother (G. B.) died of chronic glomerular nephritis in 1931. The patient had measles, chickenpox, mumps and diphtheria in early childhood and influenza in 1918 at the age of 9 years. Present History: The onset of symptoms came about a week prior to his admission, with malaise and weakness. Three nights later he had a severe headache and was dizzy. This was accompanied by epistaxis. The next morning he had epigastric pain, vomited and had three loose bowel movements.

On physical examination the patient was acutely ill, restless and bleeding from the gums and had a uremic breath. The fundi showed hypertensive retinitis. The heart and lungs were essentially normal. The blood pressure was 150 systolic, 100 diastolic on admission and rose to 166 systolic, 100 diastolic before death. The blood had a hemoglobin content of 80 per cent, 4,500,000 red blood cells, 7,800 white blood cells, with a normal differential count. The blood chemistry showed a urea nitrogen of 145 mg. and creatinine of 4.6 mg. per hundred cubic centimeters of blood. The urine showed a specific gravity of from 1,004 to 1,006, albumin 1 plus, few casts but no red blood cells. The spinal fluid on puncture showed a pressure of 12 mg. of mercury but otherwise was normal. The electrocardiogram was normal. A diagnosis of chronic glomerular nephritis was made and symptomatic therapy instituted. However, the patient failed rapidly. He became more drowsy and vomited at frequent intervals. The urea nitrogen kept mounting until it reached 241 mg. per hundred cubic centimeters of blood. Auricular fibrillation developed; he lapsed into coma and died August 18.

Permission for autopsy was not obtained.

CASE 3.—H. B., aged 23, the third brother, a grocer, was admitted to the Bronx Hospital in the service of Dr. Henry Schumer Nov. 17, 1936, and died November 30. He had measles as a child, was treated in the Massachusetts General Hospital in December 1928 at the age of 17 for Marie Strümpell's disease and had an appendectomy in 1929. However, up to Nov. 11, 1936, he was unaware that he had hypertension or nephritis. At that time he consulted a physician because of severe headache, weakness of the lower extremities, anorexia and nausea, and pallor. His symptoms became progressively worse; he became drowsy, uncooperative and irrational and was referred to the hospital.

On physical examination he was well nourished and in a semistuporous state. His edematous face had a marked waxy pallor, and there were several necrotic areas on the mucous membranes of the lips, mouth and nose. He had a dry beef-like tongue and a definite odor of urine on his breath. Respirations were of the Kussmaul type. The pupils were equal and regular and reacted to light and in accommodation. The fundi showed no evidence of hypertensive retinopathy. Examination of the heart revealed a normal sinus rhythm and no adventitious sounds. The apex was felt in the fifth interspace in the midclavicular line. There was no evidence of pericarditis. The pulse rate was 90 per minute and the blood pressure 224 systolic, 160 diastolic. The lungs, abdomen and extremities were normal. The Wassermann and Kahn reactions were negative. Examination of the urine revealed a fixed specific gravity ranging between 1,008 and 1,010, albumin ranging from a trace to 3 plus, frequent white blood cells in all specimens and a few red blood cells in the antemortem specimen. The sedimentation rate was 6 mm. in five minutes, 12 mm. in eleven minutes and

18 mm. in seventeen minutes. Examination of the blood revealed a hemoglobin content of 56 per cent; red blood cells numbered 3,380,000 and white blood cells 13,000, with a differential count of polymorphonuclear leukocytes 83 per cent, nonsegmented polymorphonuclear leukocytes 5 per cent, lymphocytes 10 per cent and monocytes 2 per cent.

The chemical examination of the blood revealed dextrose 115.6 mg. per hundred cubic centimeters, urea nitrogen ranging from 122.4 to 166 mg., nonprotein nitrogen from 153 to 231 mg., creatinine from 4.54 to 4.68 mg., phosphorus from 5.7 to 7 mg., calcium 8 mg., uric acid 6 mg. and carbon dioxide combining power 42.8 volumes per cent. The electrocardiogram revealed a sinus tachycardia and slurring of the QRS complexes.

A diagnosis of chronic glomerular nephritis and uremia was made on admission and treatment instituted. He was given dextrose parenterally, calcium gluconate, sedatives and spinal drainage to relieve the cerebral irritation, but to no avail. His temperature, which was 100.6 F. on admission, rose to 103.6 on the sixth day of his stay in the hospital and signs of pneumonia developed in both lungs, more marked on the right side. He vomited incessantly, gradually lapsed into coma and died November 30, thirteen days after his admission to the hospital.

NECROPSY

Necropsy was performed by Dr. Joseph Felsen.

Gross Pathologic Changes.—These consisted of uremic frost; left subconjunctival hemorrhage; pericholecystic adhesions; fatty liver; petechial submucosal hemorrhages of the colon; granular, cystic, contracted kidneys; bilateral bronchopneumonia, particularly of the right lung; left ventricular hypertrophy; thickening of the mitral valves, and few atheromas of the aorta.

Histopathologic Changes.—Examination of the kidney sections showed advanced changes in the glomerular tufts and small arteries. The former exhibited marked thickening of Bowman's capsule with some exudative changes. The glomerular tufts were narrowed, fibrotic or completely obliterated by scar tissue. Varying degrees of atrophy and obliteration could be seen in different parts of the section. The parenchyma was the seat of advanced degenerative changes with dilatation of the tubules and atrophy of the lining epithelium. In some areas the atrophic and somewhat cystic tubules were filled with a hyaline material. There was a generalized and diffuse increase in the connective tissue between the tubules, surviving glomeruli and arterioles. There was a striking similarity in the pathologic picture seen in the kidney sections of the brother G. B., particularly in the thickening of Bowman's capsule.

COMMENT

In comparing the three cases, one is struck with the similarity of the age, the symptoms, the apparent suddenness of onset and the short duration of illness. Careful inquiry revealed that none of the three brothers had scarlet fever and that at no time did they have a simultaneous illness as in the cases reported by Ernestene,⁹ Thomson and Macauley¹⁰ or in one of the cases of Eason and his associates.⁷

To explain the etiology one may postulate that (a) the appearance of chronic glomerulonephritis in the three brothers may have been a coincidence, (b) that all three had had a similar unrecognized infection of some sort in childhood, or (c) that their kidneys were either hypogenetic or else were the so-called *locus minoris resistentiae* and hence were more susceptible to disease.

Coincidence may be excluded, there being too many factors to make it at all likely. Repeated questioning of the parents failed to elicit a history of scarlatina or any other illness that the three boys might have had either simultaneously or successively, except that they all suffered from "nasal trouble." Hence a common infection as in the cases of Ernestene, Thomson and Macauley, and Eason can be ruled out. As there was no evidence of hypogenesis on autopsy (it has been found that hypo-

genetic kidneys are more prone to infection and nephritis than normal kidneys), one is forced to accept the hypothesis that their kidneys were the *locus minoris resistentiae* and hence more susceptible to nephritis. The parents, surviving brother and three sisters were studied carefully to rule out latent nephritis. Repeated examinations of the urine, chemical analyses of the blood and urea clearance tests revealed no demonstrable renal disorder.

To determine whether the surviving members of the family had increased sensitivity (allergy) to the hemolytic streptococcus or to a product of its growth, we repeated the experiment of Longcope,⁹ who found in experiments with intradermal tests of bouillon filtrates of hemolytic streptococci that patients with acute and subacute glomerulonephritis gave exaggerated cutaneous reactions. This is not a temporary condition but may exist several years after the patient has recovered from the attack of nephritis.

A bouillon filtrate of hemolytic streptococci was made, and the mother, four children and four controls were given intradermal tests. The four controls, the mother and the four children all gave positive cutaneous reactions to the 1:100 dilution of the filtrate but negative reactions to 1:200 dilution of the filtrate. We conclude, therefore, that the skin of none of the tested subjects was sensitive to the bouillon filtrate of the hemolytic streptococcus.

To make sure that a food sensitivity did not exist in the surviving members of this family, the youngest brother and sister were referred to the department of allergy for testing of the skin. The usual routine food and epidermal intradermal tests resulted in entirely negative reactions.

None of the surviving members of the family gave evidence of vascular spasm. The youngest daughter, a highly neurotic girl of 19, complained of coldness of the extremities, mottling of the skin and tingling of the fingers. She could obliterate her radial pulse by holding her breath (Valsalva experiment). Very thorough study by the peripheral vascular department at the Bronx Hospital revealed no evidence of vascular spasm, however.

While the pathogenesis of glomerulonephritis is not entirely clear, there are certain accumulated data which tend to point to the following conclusions:

The glomerular lesions of acute glomerulonephritis are not due to direct invasion of the kidneys by streptococci or other bacteria but to the injury of the glomeruli by their toxic product. This would account for the fact that acute glomerulonephritis is very rarely seen in the early stages of scarlet fever, tonsillar sepsis or puerperal sepsis, despite the fact that the blood and urine may harbor numerous virulent micro-organisms. This hypothesis is further confirmed by the fact that Wilson,¹⁰ Longcope and his co-workers,¹¹ Friedemann and Deicher¹² and other observers have failed to find micro-organisms in the blood or urine in cases of acute glomerulonephritis.

The discovery by the Dicks and Dochez of the scarlatinal streptococcus with its powerful toxin, and the demonstration of the presence of the toxin of the scar-

latinal streptococcus in the urine of some patients with scarlet fever by Trask and Blake¹³ seem to prove that bacterial infections complicated by glomerulonephritis produce toxic substances which pass through the kidney into the urine. The glomerular capillaries are probably injured during the excretion of these toxic substances.

But this conception does not explain the fact that the glomerulonephritis in scarlet fever or that following tonsillitis comes during convalescence and not during the height of the disease, as manifested by fever, rash and the other symptoms of toxemia.

To explain this, Béla Schick¹⁴ and later Longcope⁹ suggested that the renal complication of glomerulonephritis depends on the development of a hypersensitive state (allergy) in the process of immunization to the primary infection. Attempts to produce glomerulonephritis experimentally in sensitized animals by Longcope and Lukens,¹⁵ Duval and Hibbard,¹⁶ Long and Finner¹⁷ and Bell and Clawson¹⁸ seem to bear out this contention. Further study, however, is necessary to determine whether the glomerular lesions produced are identical with the lesions in the human disease.

In line with these hypotheses we believe that (a) our patients were born with kidneys that were the *locus minoris resistentiae* and that (b) the glomerulonephritis of these patients was the result of a hypersensitivity of the kidney tissues to bacterial toxins, possibly from a sinusitis ("history of chronic nose trouble").

RADIATION SICKNESS

TREATMENT WITH NICOTINIC ACID

J. WALLACE GRAHAM, M.D., M.R.C.P.

TORONTO

In spite of increasing knowledge and improved technic in the use of roentgen rays, radiation sickness continues to be a major problem for those who are using high voltage therapy. With the addition of nausea and vomiting to the discomfort of those already suffering from cancer, it is not surprising that some patients prefer to discontinue their treatment rather than suffer this additional distress. The problem became manifest as soon as roentgen therapy was introduced and immediately various investigators attempted to find the cause and to formulate a treatment.

In 1907 Edsall and Pemberton¹ declared that the vomiting was toxic in origin, owing to products of decomposition from tissue destruction. Pfahler,² on the other hand, blamed gases produced by the spark of the machines and to some extent was supported by Friedman and Drinker,³ who measured the ions and gases

in treatment rooms and found that positive ions were predominant, with ozone and nitrous gases. They advocated better ventilation in treatment rooms and the use of masks; these measures have been tried here with but little success. Lange⁴ in 1916 brought forward the acidosis theory that cellular disintegration or an increase in catabolic cellular activity gave rise to acidosis and radiation sickness. Sodium bicarbonate was recommended in treatment but was universally unsuccessful.

Hall and Whipple⁵ in 1919 exposed animals to lethal doses of x-ray and noted an increase in nitrogen elimination and in the nonprotein nitrogen of the blood preceding death. They found epithelial injury in the mucosa of the intestine and suggested that injury to these cells was the cause of the general intoxication. Denis, Martin and Aldrich⁶ obtained similar results in rabbits and found that reactions occurred only in animals in which some portion of the intestine was exposed. Irradiation of the intestine invariably gave severe intoxication, but therapy to the thighs, neck or chest produced no symptoms. Most of the rabbits showed acidosis with a fall in alkali reserve; therefore they concluded that, as well as intestinal damage, acidosis plays a part in the reaction. Two years later Golden⁷ was unable to confirm the acidosis theory: he reported four cases of radiation sickness in man and three in dogs but with no change in the plasma carbon dioxide combining power.

In 1907 Warthin⁸ reported kidney changes—so-called roentgen nephritis, but McQuarrie and Whipple⁹ in following this lead were able to produce fatal x-ray intoxication without the slightest disturbance of kidney function. Further work on the intestinal theory was then reported by Warren and Whipple,¹⁰ who suggested that roentgen sickness resembled the intoxication of intestinal obstruction. Marked necrosis was demonstrated in the small intestine from a lethal dose of x-rays. A similar dose over the thorax had no effect. They found no changes in blood, bone marrow or lymphatic tissue, and the liver showed no disturbance in function and no change in the level of bile acid and bile pigment output.

Reduction of toxemia by surgical means was then advocated by Beck,¹¹ who was impressed by the theory of formation of toxic substances from a breakdown of cancer tissue. His method involved surgical exposure of the tumor, removal of as much as possible of the growth, and direct irradiation of the remainder through the open wound. By this method less radiation was required, less breakdown of tissue occurred, and toxic products drained into the dressing. He carried out this major procedure in more than a hundred cases with no resultant toxemia.

Sir Humphry Rolleston¹² agreed with the theory of a flooding of the circulation with proteins liberated by the destruction of cells. He felt that cellular change need not be localized in the intestine but that destruction of large growths in the neck or in any other region might be followed by constitutional symptoms. Corti and Pucher¹³ disagreed with these observations and suggested that radiation sickness was not due to excessive cell catabolism. They found the most intense reaction in cases in which there was a low nitrogen output, and in three cases they also demonstrated a retention of chlorides. Cameron and McMillan¹⁴ also found a retention of chlorides, particularly if the upper part of the abdomen was irradiated, and stated that the feeding of chlorides before and during treatment prevented or lessened the sickness. Schlagintweit and Sielmann¹⁵ claimed that the decrease in blood chloride was due to dilution and stated that full relief was obtained by giving sodium chloride intravenously or by mouth.

liver, pancreas and kidneys. They found no evidence of nitrogen retention and were unable to support the uremic theory.

In 1935 Holmes and Hunter¹⁸ compared radiation sickness to catarrhal jaundice and, without sufficient evidence, suggested a temporary interference with liver function. They claimed that the reaction occurs when treatment is close to the liver and advocated an increased carbohydrate intake: candy between meals, fruit juices and lactose, and intravenous 5 per cent dextrose if necessary. In our experience an increased oral administration of carbohydrate is impossible to patients suffering from radiation sickness. In 1936 Richards and Peters¹⁹ and Popp²⁰ found that pentobarbital sodium was effective in controlling a large number of cases. In the same year intramuscular liver was advocated by Young.²¹

Last year Martin and Moursund²² reviewed the various claims as to the cause of radiation sickness and

Andersen and Kohlmann¹⁶ advanced the uremic theory. They found changes in the mineral content of the blood: blood calcium was increased; potassium was decreased at first and became normal in twenty-four hours; blood sodium was lowered for several days. They suggested that the alteration in blood mineral content was due to vagal stimulation and recommended calcium salts in treatment.

Dodds and Webster¹⁷ investigated metabolic changes and found that irradiation of the head, thorax and limbs had no effect. Radiation of the abdomen and spleen, however, gave definite urinary and blood changes. A sudden fall occurred in urinary urea, uric acid, ammonia, titratable acidity, creatinine, total nitrogen and phosphates, with a return to normal in three days. The blood showed a marked decrease in urea content. These effects were attributed to a temporary inhibition of the functions of the principal abdominal glands, such as the

suggested that some portion of the intestinal tract or the parotid gland must be included in the treated area for symptoms to be produced. They pointed out that radiation sickness resembles the effect of vitamin B₁ deficiency and also that vitamin B₁ protects guinea pigs against small doses of abdominal radiation but that, as the doses are increased, it becomes less effective. Other investigators have suggested as causative factors a decrease in blood cholesterol, the presence of an alkalosis and the effect of allergic phenomena. These diverse and sometimes contradictory theories with regard to etiology indicate that the mechanism of radiation sickness is still undefined. With regard to treatment, pentobarbital sodium and intramuscular liver are the only remedial measures which have been found useful in this clinic.

In an effort to confirm some of the metabolic changes that have been mentioned, the blood of ten patients undergoing intensive radiation therapy over a period of weeks was studied; in five cases the blood was studied before as well as after treatment. Eight of the ten

patients were suffering from severe nausea and vomiting when the postirradiation blood was taken. Table 1 shows the results of blood and urinary examination in these cases.

No evidence of nitrogen retention was found, the level of nonprotein nitrogen and creatinine in the blood being normal in the ten cases studied. The acidosis theory could not be confirmed, the serum carbon dioxide combining power remaining within normal

TABLE 2.—Incidence of Radiation Sickness in Relation to Area Irradiated

Area	Number of Patients	Patients Sick	
		No.	Per Cent
Abdomen.....	90	33	36.6
Chest.....	21	5	23.8
Head and neck.....	25	6	24.0
Extremities.....	8	0	0

limits. No evidence of liver damage was obtained from the blood, van den Bergh test or urinary bile and urobilin. Dextrose tolerance tests were attempted but had to be abandoned, as the patients could not retain the dextrose. However, fasting blood sugar levels were normal in all cases. Decreased blood cholesterol was obviously not the cause of radiation sickness in this series. Blood chlorides were also found to be within normal limits.

In a similar group of cases, no significant changes were found in the blood sodium or potassium. Blood potassium levels were normal in nine of twelve cases after radiation therapy. Although the postirradiation blood sodium was low in eight cases, it was equally low in five of these before irradiation.

The necrotic changes observed²³ in the intestinal mucosa of animals subjected to lethal doses of x-rays were not found in human cases after high voltage treatment. Ten patients who died while receiving intensive therapy to the abdomen were examined post mortem and in no case was any macroscopic lesion of the intestinal mucosa observed.

TREATMENT

In 1938 Spies, Cooper and Blankenhorn,²⁴ while studying cases of pellagra, found that these patients excreted abnormal amounts of porphyrin in the urine, which diminished when nicotinic acid was administered. Later Spies, Bean and Stone²⁵ noted a similar porphyrinuria in five of seven cases of radiation sickness. Nicotinic acid in doses of from 200 to 1,000 mg. daily was administered to these patients, and the treatment was followed by a prompt cessation of nausea, vomiting, anorexia and headache in all seven cases and a return to normal of the urinary porphyrin.

It was decided to try this drug²⁶ in a series of cases under roentgen treatment at the Ontario Institute of Radiotherapy, Toronto General Hospital. This group includes only those cases of radiation sickness in which severe nausea or nausea and vomiting were present. In

some cases in which there were large abdominal or mediastinal masses, the vomiting may have been initiated by factors other than high voltage therapy.

In the series were seventy patients, of whom nineteen were males and fifty-one females, the average age being 45 years. The sex incidence of radiation sickness was not determined, as two thirds of the male patients received radiation to the head and neck whereas the vast majority of female patients received abdominal therapy. Forty-two of the patients were in the hospital; the remainder received their treatment as outpatients. With the onset of the radiation sickness, patients were given 200 mg. of nicotinic acid three times daily. In four cases this resulted in rather severe reactions, flushing and burning of the skin and a feeling of intense heat. The dosage was reduced to 100 mg. twice or three times daily, following which only occasional slight reactions were observed. The powder was placed in half a glass of water and the patient instructed to sip it slowly over half an hour, stirring the mixture frequently. More recently we have used 30 mg. tablets, which have been administered in a similar manner.

RESULTS OF TREATMENT

In this series of cases a moderate to severe degree of radiation sickness occurred in 27.6 per cent of all the patients receiving high voltage therapy over a period of approximately six months. An additional group of 105 patients was treated with radium or telradium; only two had nausea and vomiting and in one of these vomiting was initiated by the anesthetic. Owing to the relatively short period of exposure and the usual areas of application, radium would appear to play no prominent part in radiation sickness. The incidence of radiation sickness was greater in cases in which 400 kilovolt therapy was administered than in those in which 200 kilovolt was given, but the difference is not significant, as the first group includes most of the abdominal cases and those receiving more intensive treatment.

Following nicotinic acid therapy a result was classed as excellent if all symptoms were cured, good if vomiting stopped and some slight nausea remained, fair for cases in which vomiting was decreased to an occasional incident, and failure when the drug had little or no

TABLE 3.—Effect of Nicotinic Acid in Relation to Area Irradiated

Area Irradiated	Result			
	Excellent	Good	Fair	Failure
Abdomen.....	13	19	4	5
Chest.....	1	5	3	2

Chest and abdomen.....	0	0	2	0

effect. Of seventy cases 27.1 per cent showed excellent results and 47.2 per cent good. In other words, the drug was definitely effective in 74.3 per cent of this group of cases. A fair result was obtained in 14.3 per cent, and in 11.4 per cent nicotinic acid failed in treatment. With regard to the failures in treatment, it would seem that the condition of the patient was a definite factor. Two of the failures were in cases of Hodgkin's disease, one with large abdominal masses and the other with massive mediastinal glands. Three of the group had primary cancer of the breast, one with

26. The nicotinic acid was supplied by British Drug Houses (Canada) Ltd., Toronto.

secondaries in the hip and spine, another with secondaries in the spine and widespread secondaries in both lungs, and the third with widespread skeletal metastases. Another was a case of inoperable cancer of the ovary with large abdominal masses and secondaries in the omentum. In four of the cases which showed excellent results, nicotinic acid was discontinued after the symptoms disappeared. The vomiting returned but ceased when the drug was administered again. Several patients who returned for a second series of radiation therapy asked for the "capsules."

Porphyrins were estimated qualitatively in the urine according to the method of Beckh, Ellinger and Spies.²⁷ The porphyrins excreted are said to be coproporphyrins I and III, both of which are abnormal in porphyrin metabolism.²⁴ Of fifty-two cases on which porphyrin estimations were made, only ten showed a material increase in porphyrinuria; all but one of these returned to normal after the administration of nicotinic acid. Even when the excretion of porphyrin appeared to be within normal limits, in most cases it was decreased when nicotinic acid was given. However, in this series of cases the degree of radiation sickness and response to nicotinic acid therapy did not seem to have any direct relation to porphyrin excretion.

COMMENT

The cause of radiation sickness has not been determined, but the absorption of toxic substances from the breakdown of tissue cells would seem to be a justifiable theory. But the destruction of abnormal tissues is not necessary, as in four cases in this group sickness occurred in conditions such as therapy for sterilization. The psychic factor must always be kept in mind, though it would seem to play only a subsidiary part. A study of the cases in this series confirms the earlier reports that radiation sickness is more apt to occur when the abdomen is included in the area irradiated (table 2).

Although not reported in animal experiments,²⁸ true radiation sickness does occur in irradiation of the chest, head and neck; but a greater number of x-rays is required before sickness develops. Of fifteen patients who had radiation sickness with less than 600 roentgens, thirteen received abdominal therapy and two chest irradiation. Sickness following radiation therapy is not only more frequent in abdominal conditions but it occurs with less exposure.

The beneficial effects of nicotinic acid therapy would appear to have no relation to the area irradiated (table 3). Although in the majority of failures abdominal irradiation was given, it is also true that abdominal therapy was given in a similar percentage of cases showing excellent results; the area of application would not appear to be the major factor. As already pointed out, six of the eight cases in which failure resulted were complicated by widespread metastases which, no doubt, had an important bearing on the result.

The mode of action of nicotinic acid has not been determined. It is said to play some part in porphyrin metabolism, but in this series of cases no evidence was found which would relate radiation sickness to abnormal porphyrin excretion. Only a small percentage of these cases showed any considerable rise in porphyrin excretion, and this had no direct relation to the degree of sickness or to improvement with therapy.

Some explanation for this abnormal pigment metabolism may be found in the work of Rimington,²⁹ who observed that many states of fever or infection lead to an increased porphyrin output. The increased excretion is attributed to a disturbance of hematopoiesis or liver function. It has been shown that coproporphyrin I cannot be derived from a breakdown of red blood cells but must arise from derangement of hematopoietic processes in bone marrow. Coproporphyrin III has been found to be associated with some impairment of hepatic function such as cirrhosis of the liver or in toxic reactions such as may be caused by arsphenamine or lead. The same author³⁰ suggests that urinary porphyrin can be taken as an index of the extent of normal hematopoietic activity and that disturbances of this activity will lead to the excretion in the urine of abnormal quantities and types of porphyrin. Such disturbances might well occur during intensive irradiation of areas involving the bone marrow.

CONCLUSIONS

Radiation sickness continues to be a major problem in roentgen therapy. Distressing symptoms of nausea and vomiting develop in 27.6 per cent of patients receiving high voltage radiation. The cause and mechanism of the reaction are unknown and no evidence has been found to support theories regarding such etiologic factors as nitrogen retention and uremia, acidosis, alkalosis, liver damage, hypoglycemia, decreased blood cholesterol, retention of chlorides or injury to the intestinal epithelium.

Radiation sickness not only occurs more frequently in abdominal therapy but it also occurs with less exposure to x-rays. True radiation sickness does occur, however, in irradiation of other parts of the body.

Results from nicotinic acid therapy would appear to be better than from pentobarbital sodium or intramuscular liver. Ease of administration with no unpleasant after-effects is definitely advantageous. In those cases which failed to respond to nicotinic acid therapy the condition of the patient and the advanced stage of the disease seemed to be greater factors than the particular area irradiated.

The mode of action of nicotinic acid has not been determined, but no direct relation to porphyrin metabolism could be shown. It is suggested that the abnormal excretion of porphyrin is related to a disturbance of hematopoietic activity or of liver function.

Blood Groups in Relation to Legal Medicine.—By means of the genetic formulas and these general rules, based on experimental evidence, it is possible in a certain proportion of putative matings to establish the fact that a child could not be the offspring of a certain individual. The converse, however, is not true. In no instance can it be shown that an individual is the parent of a given child. But it is apparent that negative evidence of this sort is of great value in legal controversies involving questions of paternity or in cases where the identity of a child is in doubt, such as have occurred as a result of interchange in the infant wards of hospitals or intentionally by wetnurses.—Zinsser, Hans; Enders, John F., and Fothergill, LeRoy D.: *Immunity Principles and Application in Medicine and Public Health*, New York, Macmillan Company, 1939.

BOSTON

Rheumatoid arthritis is a chronic disease of unknown etiology. It respects neither age, sex, race nor social position, although it does affect women more frequently than men, white persons more often than Negroes and the poor more commonly than the rich. In addition to the articular involvement, which is usually symmetrical and more likely to affect small joints first, the patients complain of constitutional, vasomotor and neurologic symptoms. These associated symptoms frequently precede those referable to the skeletal system and in many instances persist throughout the course of the disease. Rheumatoid arthritis may be unrelentingly progressive from the onset but is more commonly characterized by remissions and relapses of varying degree and duration. In a small percentage of cases the remissions are complete and of years' duration; in the majority they are incomplete and short lived with recurrent symptoms and telltale evidence of previous fascial or joint involvement persisting. Irrespective of the initial course of the disease, increasing evidence of progression occurs with the passing of time, leading in many instances to partial or complete incapacitation. The economic and social problems resulting from this chronic, progressive disease are multitudinous; but they are more fully realized today than ever before. In consequence, much time and effort are being expended in the hope of obtaining a more complete biologic picture of the disease entity called rheumatoid arthritis and the patients affected.

Previous workers have offered many theories concerning the cause of rheumatoid arthritis. No one of these has been accepted, in most instances because of insufficient proof, in others because removal or correction of the supposed offending factor has failed to arrest or cure the disease with any regularity. Doubtless many of these erroneous theories represent failure to distinguish sharply between etiologic cause and contributing or precipitating factors. There is good reason to suspect that various factors may predispose the patient to an attack of rheumatoid arthritis. From the evidence at hand, however, it would appear that in addition there is necessary an x factor, the principle etiologic agent. This is as yet unknown.

In most cases of rheumatoid arthritis one can demonstrate many clinical and laboratory abnormalities which serve as evidence that the disease may be infectious in origin. The majority of workers favoring this theory consider that the hemolytic streptococcus plays an

important etiologic role, again without adequate proof. Adherents to this theory are therefore interested in the incidence of upper respiratory infections preceding the onset or an exacerbation of the disease. Experience teaches the physician that a history of such infections is not obtained with any regularity. In fact, one encounters many cases in which it is impossible to establish the existence of any of the usual preceding, contributing factors. This failure to elicit more regularly one of the usual precipitating factors impresses on the student of the disease the necessity of studying the patient as a biologic unit. A better description is needed of the host and the many environmental factors with which he has to contend.

Prior to the advent of bacteriology as an established science and the many infectious theories concerning the etiology of rheumatoid arthritis, much was written concerning the neural theory. Notable among the earlier workers who advocated such a relationship were Ord,¹ Spender,² Wichmann,³ Garrod,⁴ Jones,⁵ Bannatyne,⁶ Fuller,⁷ Duckworth,⁸ Osler,⁹ Hyde¹⁰ and McCrae.¹¹

Chart 1.—Temporal relationship between the environmental stress and the onset or exacerbations of rheumatoid arthritis. It will be noted that a significant relationship was encountered in a large number of the arthritic patients and rarely in the control group (patients with varicose ulcers).

Included among the adherents to the neural theory were those who postulated the existence of lesions of the central nervous system (chiefly because of the symmetrical joint involvement) as well as those who attributed the onset or exacerbation to some type of

emotional shock. Subsequently others¹² have suggested that emotional shock, anxiety and worry play an important role.

Specific examples are recorded in which rheumatoid arthritis came on immediately after some disturbing emotional experience.¹³ In some instances no other precipitating factor was disclosed. Experiences of this sort occurring in a disease of unknown etiology, plus the fact that many of the patients complain of vasomotor, neurologic, constitutional, cardiorespiratory and gastrointestinal symptoms not unlike those encountered in the psychoneuroses, has been largely responsible for the renewed interest displayed by internists and psychiatrists concerning this aspect of the person with rheumatoid arthritis.¹² Other workers¹⁴ have mentioned mental strains and "nervousness" as being related to the onset and relapses.

Most physicians who have cared for patients with rheumatoid arthritis have observed such temporal relationships between onset of arthritic symptoms and emotional crises. In some instances the exacerbations and remissions run remarkably parallel to changes in the environmental stress under which the patients live. Isolated personal experiences are frequently recounted at meetings. Such examples carry little weight except with the physician who has seen the phenomenon. He knows that there is a relationship but cannot prove it. It becomes a matter of personal conviction without adequate evidence. Because of such personal experiences, a simple study was planned, merely to find out how often there was a relation in time—a synchronism of social factors and arthritic symptoms.

METHODS

For this study fifty patients with typical rheumatoid arthritis were interviewed by a psychiatrist or a social worker, as chance brought them to a special follow-up clinic or to the hospital wards. They comprise a part of a series of 300 cases that have been studied in great detail and observed over a period of years, as long as eight years in some instances. An hour or longer was spent with each patient. Although the patient was encouraged to talk in his own way about his life, the questioner had points to be covered, which were the patient's birthplace, for the interest of its being American or foreign; the place of the patient among his siblings, with a brief description of the living conditions into which he was born; the age and circumstance of the beginning of school life; early emotional reactions; work history; age and circumstance of marriage; birth of children and early adjustments in married life; life events and adjustments, and the present situation. Each patient was asked if he had ever had a nervous breakdown.

The facts obtained were written on a life chart such as is used by Professor Adolf Meyer¹⁵ at the Johns

Hopkins Hospital. At some subsequent time the medical data from the hospital record were entered on the same life chart. This included all past illnesses as well as prodromal arthritic symptoms, onset of the arthritis, remissions and relapses and condition at the time of the interview. These medical facts were checked by Dr. A. O. Ludwig of the arthritis clinic.

The important thing shown when the data are recorded on such a life chart is the chronological relation between different events in the patient's life. The severity of the arthritis is indicated in black in the middle column of the life chart. Thus one can tell roughly how often the environmental burdens occurred at the time of the onset or an exacerbation of the arthritis. Obviously no definite limitation of time can

Chart 2.—Life chart of patient 13, a woman.

be set which divides the significant from the insignificant relation. In general, events falling in the same year might be judged as having a relationship. In some instances the patient himself emphasized this relationship in telling his own story. This method of study is not psychologic in any deep sense, it is more sociological because the work was done too superficially and too quickly to give any psychologic picture of the patient other than an impression of the personality concerned.

OBSERVATIONS

From a study of the life charts and the records, it seemed justifiable to divide the patients into three groups: (1) those cases which appeared to have a close temporal relationship between the life stress and the arthritis, (2) those cases in which the relationship was doubtful and (3) those cases which seemed to have no such relationship (chart 1).

Clinical Notes, Suggestions and New Instruments

AIR EMBOLISM FOLLOWING THE KNEE-CHEST POSITION

R. L. REDFIELD, M.D., AND H. R. BODINE, M.D., BUFFALO

Air embolism in obstetrics was first considered in 1829, when it was thought that the entrance of air into the uterine sinuses and veins might be a source of danger in recently delivered women. Two English physicians, Cormack in 1850 and George May in 1851, each reported three cases of air embolism following delivery. Since that time several instances of air embolism have been recorded which occurred during the performance of criminal abortion, during the use of uterine douches to loosen adherent retained placental tissue and after normal spontaneous deliveries. Patients with placenta praevia and bleeding during the latter half of pregnancy have been treated with an attempt at version and, at about the time the foot was drawn through the cervical canal, they have collapsed and died. The only cause of death to be found on the postmortem examination was air embolism.¹

In recent literature we have found instances of air embolism that were considered rather unusual because their onset was relatively late in the puerperium. In 1936 Quigley and Gaspar² described a fatal case of air embolism in a nonipara aged 26 which occurred on the eighth postpartum day after she had been in the knee-chest position for five minutes. She had delivered spontaneously and had an afebrile and uncomplicated postpartum course. She had done the knee-chest exercise twice for thirty minutes the day previous to her death. Four hours after she died an autopsy was done, which showed a moderately subinvolutus uterus containing small pieces of retained placental tissue with surrounding hemorrhages and blood clots. The right side of the heart was dilated with air and the right ovarian plexus was distended, owing to abundant air bubbles.

Another case was reported by Stroh and Olinger³ of Seattle in April 1938. A decipara aged 39 had had a normal spontaneous delivery followed by an uneventful puerperium. On the seventh day, after assuming the knee-chest position for the first time, she suddenly collapsed and died in from four to five minutes. The postmortem examination revealed extensive air embolism of the right ovarian vein, inferior vena cava and chambers of the right side of the heart. The main portion of the pulmonary artery contained only fluid blood mixed with bubbles and no clotted blood.

REPORT OF CASES

Mrs. H. L., a secundigravida aged 33, a private patient, was admitted to the Millard Fillmore Hospital in Buffalo Aug. 1, 1936, and delivered of a male infant weighing 6 pounds 8 ounces (2,948 Gm.) spontaneously without any complication. After an uneventful postpartum course she was up and walking about on the tenth day. The following day, the eleventh post partum, she entered into a convulsion five minutes after completing the knee-chest exercise. The impression of the one who first saw her was that she was having an eclamptic seizure, and she was given one-fourth grain (0.016 Gm.) of morphine sulfate and 2 cc. of 50 per cent magnesium sulfate hypodermically. This was followed by the administration of coramine. Twelve minutes after the onset of the convulsion the patient died.

The pathologist's report on the autopsy was as follows: The essential conditions at autopsy were that frothy blood was found in the chambers of the right side of the heart but very little in the chambers of the left side. The lungs showed numerous large blebs of air, and microscopic sections showed alveoli distended with air.

The uterus was filled with blood clots. Microscopic sections showed that some of the sinuses contained blood while others were empty and gaping.

All the large uterine veins contained air with a frothy appearance of the blood. This was especially marked in the iliac veins and the inferior vena cava.

The summary presents the probable source of air embolism as being through the uterine wall, possibly a softened area such as the site of the attached placenta, following the knee-chest position with ballooning of the vagina and an inrush of air into the uterine wall.

A second case of air embolism, occurring in the Millard Fillmore Hospital in October 1938, is described as follows:

E. M., a septigravida aged 30, was admitted to the obstetric outpatient department July 29, 1938. Her past history was negative for serious illnesses except that she had scarlet fever when she was a baby. The operative history was negative. She had previously had five full term pregnancies and one miscarriage without complications. All of her former deliveries were normal and uncomplicated.

Her last normal menstrual period was Feb. 15, 1938, and from that date to July 29 she had experienced irregular vaginal bleeding lasting about two days at a time and occurring about every three weeks. In the latter part of June she had what she termed a severe hemorrhage, after which she passed small clots infrequently. Her last bleeding had occurred about ten days prior to her coming to the clinic. This was accompanied by cramping pains, which subsided after some blood was passed. There were no toxic symptoms and her only other complaint was varicosities of the legs.

Owing to her history of bleeding, she was started on injections of an anterior pituitary-like substance, 1 cc. every ten days.

The second visit to the antepartum clinic was August 9. Her blood pressure was 106 systolic 72 diastolic. The Wassermann and Kline reactions were negative. Urinalysis was negative. The basal metabolic rate was plus 8.4 per cent. Pelvic measurements were normal. There had been no bleeding since her first visit.

September 21 she reported that there had been bleeding for thirty-six hours, beginning September 14, which was accompanied by cramping in the lower part of the abdomen. She went to bed for two days and the symptoms ceased. She was instructed to take thyroid 1 grain (0.065 Gm.) every other day.

October 5 she stated that there had been no bleeding since the previous visit. Her total gain was 40 pounds (18 Kg.).

The patient was admitted to the hospital on October 22 at 11:15 p. m., after being in labor for an hour and fifteen minutes. At the onset of the uterine contractions she had noticed considerable bloody discharge. Vaginal examination revealed that the cervix was dilated four fingerbreadths and completely effaced. The fetal heart tones were in the right lower quadrant and of good quality. The blood pressure was 115 systolic 70 diastolic. The position of the sagittal suture and fontanelles indicated an occipitodextrotransverse position.

At 12:15 a. m., October 23, the cervix was dilated five or six fingerbreadths. The patient was delivered by version and extraction at 1:17. The infant was a normal 7 pound 7 ounce (3,374 Gm.) female. The total duration of the labor was three hours and seventeen minutes. Because of the history of bleeding during the pregnancy, the uterus was explored during the version for the position of the placenta, and it was found to be located high on the posterior wall. The placenta was delivered intact and there was no evidence of premature separation, as might be indicated by old clots or darkened areas on the uterine surface of the placenta. There was evidence of chronic cystic cervicitis, so the margins of the cervix were debrided and the cervix was repaired bilaterally.

Ergotrate (a malcate of an ergot base) $\frac{1}{20}$ grain (0.2 mg.) was given intramuscularly immediately after the placenta was delivered, and the same dosage was given by mouth every eight hours for six doses thereafter because of her parity and the fact that the patient had a rather atonic uterus.

The catheterized specimen of urine obtained at the time of delivery showed a faint trace of albumin and a few leukocytes. The blood count postpartum was, hemoglobin 74 per cent and erythrocytes 3,700,000.

From the Departments of Obstetrics and Pathology, Millard Fillmore Hospital.

1. Gough, J. A.: Air Embolism in Obstetrics, Surg., Gynec. & Obst. 39: 27 (July) 1924.

2. Quigley, J. K., and Gaspar, Istvan: Fatal Air Embolism on the Eighth Day of the Puerperium, Am. J. Obst. & Gynec. 32: 1054-1057 (Dec.) 1936.

3. Stroh, J. E., and Olinger, M. T.: Air Embolism, Am. J. Obst. & Gynec. 35: 711-712 (April) 1938.

The postpartum course was uneventful and afebrile, the highest temperature being 99 F. On the seventh day she did the knee-chest exercise for three minutes. At 9:20 a. m. on the eighth day she did the knee-chest position for five minutes. On coming down from this position, the patient gasped and then complained of feeling faint. Generalized clonic movements promptly developed and her respirations became stertorous and gurgling. She was seen immediately by two house physicians, who found her in a spastic attitude with the knee and elbow joints extended and her jaws firmly set. There was extreme pallor in the extremities, and her face and nail beds were cyanotic. Respirations became very slow and finally gasping. She then became relaxed and pulseless with no action of the heart detected on auscultation. At 9:40 approximately fifteen minutes after completing the knee-chest exercise, she died. Epinephrine was injected into the heart muscle with no response.

An autopsy was performed and the pathologist's report was as follows:

The body was well developed and well nourished. There was no rigor mortis, lividity, edema or jaundice and the body was still warm. There were no special marks of interest to be seen. Both breasts were well filled and lactating.

The pupils were equal and regular. The nose, mouth, throat and ears were normal on examination. The neck showed nothing of interest.

The thorax and abdomen were opened in the usual manner. The organs and blood vessels were carefully examined before an incision was made into any organ or before any part was removed.

Examination of the venous system revealed the presence of air under pressure in the right side of the heart and the beginning of the pulmonary artery. When an incision was made into the pulmonary artery and the right side of the heart an audible escape of air was noticed. Frothy blood also exuded from the incision, but the quantity of blood itself was markedly diminished. The left side of the heart was empty and did not contain blood. The inferior vena cava and the iliac, renal, ovarian and uterine veins were all distended with air and frothy blood.

The uterine veins were filled with air bubbles and any manipulation of the uterus or compression caused the further entry of air into the veins. Bubbles of air could be seen entering the vessels as this was done. The uterus itself was boggy and enlarged. The fundus reached almost to the level of the umbilicus. As the uterine wall was carefully opened, air bubbles escaped from the cut surface. Further section showed a mass of membrane attached to the posterior uterine wall and a blood clot approximately $2\frac{1}{2}$ inches in diameter with wide open venous sinuses of the uterus beneath. These sinuses were easily demonstrated by probing. All veins, with the exception of the portal system veins, were air containing to such a degree that distention was the proper term for description. No thrombi or postmortem clots were found. This unusually careful examination of the venous portion of the circulatory system was made because of the history of the patient's having assumed the knee-chest position just previous to her sudden death.

The thoracic organs were examined next. No pleural fluid or adhesions were found on either side. The right lung weighed 440 Gm. and the left lung 450 Gm. The tissue appeared well areated and was grossly normal in appearance. Cut sections revealed the presence of numerous small areas that were darker than the surrounding tissue and appeared hemorrhagic. No air embolism in the lung tissue could be demonstrated.

The heart was of normal size and consistency. The chambers of the right side of the heart contained air. Those on the left side were free of both air and blood and were in a state of contraction. The heart musculature was a homogeneously beefy red. All valves appeared normal and no sclerosis of vessel orifices could be seen. The measurements of both musculature and heart valves were normal: mitral valve, 9 cm.; aortic valve, 7 cm.; tricuspid valve, 11 cm.; pulmonary valve, 8 cm.; thickness of left ventricle, 1.2 cm.; thickness of right ventricle, 0.3 cm.

The abdominal organs were essentially normal except for the venous system and the uterus, as previously mentioned.

The liver weighed 2,130 Gm. and was slightly darker than normal. Cut sections showed nothing of further interest.

The gastrointestinal tract was entirely normal from the esophagus to its termination.

The spleen weighed 275 Gm. and was the color of a dark nutmeg on cross section. No unusual gross characteristics were observed.

The left kidney weighed 145 Gm. and the right kidney 230 Gm. Neither kidney was grossly abnormal. Both capsules stripped readily. The ureters were normal, as was the bladder.

The uterus was approximately the size of two fists and reached to just below the umbilicus. It was flabby and doughy on palpation and contained membranous tissue mixed with a partially organized blood clot of the size and appearance previously described. The ovaries and tubes showed nothing of interest. The vaginal vault was opened and the cervix showed a stellate incision with sutures still in place.

Microscopic studies added nothing except to confirm the presence of membrane elements in the uterus and also to show a very moderate focal infarction of the lung tissue. Fatty metamorphosis of the liver was present.

The mechanics involved appeared to depend on the following factors: (1) retained membrane tissue, (2) failure of the uterus to involute properly, (3) the knee-chest position, allowing ballooning of the vagina with air and an increase of the air pressure within the uterine cavity and possibly ballooning of an atonic uterus itself, and (4) entry of air into gaping uterine sinuses. These four factors were present in this case, so that the complete story is that of air entering the uterine sinuses, held open by retained membrane and partially organized blood clot, following the knee-chest position with its attendant increase of the intravaginal and intra-uterine air pressure. Air then entered the uterine veins, iliac veins, inferior vena cava, ovarian and renal veins and the right side of the heart itself. The presence of air in all these veins including the uterine wall is demonstrated in this instance.

The mechanics of air embolism can be compared with that of a bellows. A woman in the knee-chest posture, having the labia separated, permits an inflow of air to the vagina and in some cases the uterus. When she descends from the posture the labia are closed and, with the collapse of the vaginal walls and the uterus, air is forced into the open uterine sinuses if it cannot escape through the vaginal orifice below.

COMMENT

Characteristics common to these cases of air embolism are multiparity and the performance of the knee-chest exercise immediately prior to the accident, and in all but one there was retention of blood clots or secundines. According to the literature, air embolism is a rare occurrence in the late puerperium of obstetric patients, but if something could be done to avoid these catastrophes another step would be made toward eliminating a fraction of maternal mortality.

Multiparity may be a predisposing cause of these accidents owing to the fact that the uterus is slower in its involution and does not contract as readily as in the primipara. This makes for the collection of small quantities of blood in the uterine cavity and the formation of clots which can act as temporary obstacles to the closure of uterine sinus openings. When these clots later break away they leave open veins which may serve as the portal of entry for air. This influence of multiparity is one over which there is little control unless it might be the administration of oxytocics during the puerperium, and this was done for the patient whose case we have reported.

The retention of membrane or small pieces of placenta in the uterus is partially avoidable by proper and careful technique in the conduct of the third stage. We believe that the course of the third stage should not be hurried. Even with the most careful attention to this phase of a delivery one cannot always know whether a small fragment of membrane remains in the uterus unless it is large enough to suggest its presence by causing some unusual amount of bleeding. Emphasis is warranted on the inspection of the placenta for any small missing portion.

The use of the knee-chest posture is a factor in the cause of air embolism over which there is complete control. We feel that this case, with the three others referred to, should leave

little doubt in any one's mind that the knee-chest exercise was the exciting cause of air embolism. The knee-chest position is a time honored procedure in the puerperal conduct of obstetric patients, but its benefits are very dubious. Many women who have meticulously followed their physician's instructions in the performance of the knee-chest exercises are found to have retroverted uteri. Postural exercises may be a help toward restoring the uterus to its normal position, but it is generally conceded by obstetricians and gynecologists that this replacement is dependent more on the inherent elasticity of the fibrous tissues making up the supportive structures of the uterus and the bladder. The elimination of trauma to the parturient woman, as far as this is compatible with good obstetric management, will probably do more to improve uterine displacement than all the various exercises in the puerperium. If there is any benefit to be gained by postural maneuvers, it would seem better merely to have these patients lie on the abdomen for longer periods of time than to have them assume the more difficult knee-chest posture for a brief period two or three times a day.

Our observation of the two cases of air embolism following the knee-chest position in our hospital and the reports of the other two cases in the recent literature forces us to conclude that there is a definite element of danger in such postural exercises whereby air is allowed to enter the vagina and probably the uterus in more instances than one realizes. Because of this danger we advocate discontinuing the knee-chest exercises, at least in the early weeks of the puerperium.

APPARENT CURE OF PRIMARY CARCINOMA OF THE LUNG BY PNEUMONECTOMY

CASE REPORT OF A FIVE YEAR FOLLOW-UP STUDY

RICHARD H. OVERHOLT, M.D., BOSTON

It has been demonstrated that an entire lung in man may be excised successfully. It has also been shown from early follow-up studies that such a procedure is not necessarily incompatible with a reasonable degree of good health. An increasing number of patients with primary carcinoma are being placed under the care of a thoracic surgeon at a time when it is impossible to demonstrate that the tumor has spread beyond the lung by our present methods of investigation. Thoracic exploration is being carried out more frequently, and my own experience suggests that the number of resectable lesions is steadily increasing. It has not been demonstrated, however, how many of these cases, which seem operable and in which no gross evidence of mediastinal extension has taken place when surgical exploration is carried out, will eventually result in death from metastatic disease. Many years will be required to answer this question. Since the first successful operations of this kind were done as recently as 1933 by Graham,¹ Rienhoff² and Overholt,³ records of more than a hundred other cases can be found in the literature.⁴ These publications concerned themselves with reports on the operation itself and immediate results. Obviously, appraisals of late results are of vital importance. Up to the present time a record has not appeared in the literature of the condition of a patient five years after pneumonectomy for primary lung cancer.

REPORT OF CASE

Mrs. A. T., aged 37, presented herself Dec. 2, 1938, for a follow-up examination, this date being five years and one month after she had been treated for a primary bronchiogenic carcinoma of the right lung by right pneumonectomy.

From the New England Deaconess Hospital, Boston.

1. Graham, E. A., and Singer, J. J.: Successful Removal of an Entire Lung for Carcinoma of the Bronchus, *J. A. M. A.* 101:1371 (Oct. 28) 1933.

2. Rienhoff, W. F., Jr.: Pneumonectomy: A Preliminary Report of the Operative Technique in Two Successful Cases, *Bull. Johns Hopkins Hosp.* 53:390 (Dec.) 1933.

3. Overholt, R. H.: Total Removal of Right Lung for Carcinoma: Report of a Successful Case, *J. Thoracic Surg.* 4:196 (Dec.) 1934.

4. Overholt, R. H.: Pneumonectomy for Malignant and Suppurative Disease of the Lung, to be published.

Patient's Report.—The patient said that she had been in good health since her discharge from the hospital. She had not had a single day's illness since that time and her only period of confinement was a brief one following contusions suffered in an automobile accident in 1936. She had been exceptionally free of colds. Symptoms such as cough, expectoration or hemoptysis had not been experienced since the operation. The patient considered that she was able physically to accomplish as much as she did before the onset of symptoms in the spring of 1933. After prolonged exertion she occasionally has some discomfort in the back and right shoulder. The patient does all the housework required for a family of four. Going up and down stairs caused no dyspnea. Daily walks of from 1 to 2 miles were taken for exercise.

Examination.—The general appearance and the state of nutrition of the patient were good. Fully dressed, there was no apparent deformity (fig. 1). The color of the skin was normal

Fig. 1.—Patient five years and one month after treatment for primary carcinoma of the lung by total removal of the right lung.

and there was no cyanosis. The fingers and toes were not clubbed. The general physical examination was essentially negative except for the chest. There was no evidence of metastatic disease. There were no enlarged lymphatic glands. The right side of the chest was smaller than the left, and healed anterior (pneumonectomy) and posterior (thoracoplasty) scars were present. There was a slight thoracic scoliosis with convexity toward the right. The shoulder motion was not limited. The trachea was in the midline. Expansion of the right side of the chest was limited. Percussion and auscultation of the left side of the chest revealed no abnormality. Breath sounds over the right side of the chest had a bronchial quality diminishing in intensity as one listened at greater distances from the midline. The position of the heart and its sounds were normal. The weight was 150 pounds (68 Kg.) as opposed to 88 pounds (40 Kg.) at the time of operation. The blood pressure was 142 systolic, 90 diastolic, pulse 96, respiratory rate 18. After the patient had gone up two flights of stairs (thirty-four steps) the pulse rose to 118 and the respiratory rate to 22. Within four minutes these rates returned to the resting level. The vital capacity was 1,050 cc. as compared to the preoperative test of 1,600 cc.

An electrocardiogram was interpreted by Dr. Lowrey F. Davenport as follows: The rate was 93; the rhythm normal. The auriculoventricular and interventricular conduction time

was normal. In lead 3 there was a phasic variation in the amplitude of the QRS complex. On expiration the QRS complexes became almost iso-electric. On inspiration the amplitude was greater and varied from plus 4 to plus 9 mm. T₃ was slightly inverted. In lead 4 there was also the same phasic variation in the amplitude of the QRS waves with respiration along with changes in the T wave from upright, to flat, to inverted. The exact phase of respiration was not determined in lead 4. The conclusion was that these changes were consistent with a shift of the heart with respiration.

A roentgenogram of the chest showed an alteration in the right thoracic cage (previous eight-rib thoracoplasty) with a homogeneous density between the right border of the vertebral column and the regenerated rib segments. The heart was of normal size and appeared in normal position. The left lung field was clear (fig. 2).

Synopsis of Past Medical History: A detailed case report has been published elsewhere.³ Symptoms of cough, expectoration, occasional hemoptysis, chills and fever of four months' duration preceded hospital admission. The general and local signs were principally those of pulmonary suppuration incidental to bronchial obstruction. X-ray examination revealed a tangerine-sized mass in the right lung near the hilus. On bronchoscopy, the right main stem bronchus was found to be closed just below the upper lobe orifice presumably from extrinsic pressure. A specimen taken from this area failed to show tumor cells. Thoracic exploration was performed Nov.

2, 1933, and a firm mass was found in the substance of the right lung near the hilus. There was no evidence of mediastinal glandular involvement. The right lung was excised and the wound closed without drainage.

Within the removed lung a moderately firm circumscribed tumor mass was found which measured 4 cm. in diameter. Tumor tissue filled the right lower main bronchus and compressed the surrounding lung tissue.

The microscopic examination of the tumor was made by Dr. Shields Warren, who reported that there was relatively little invasion of the surrounding tissue. The cells were arranged in anastomosing strands from two to eight cells wide with a fair amount of hyalin. The stroma was moderately vascularized. The tumor cells were principally columnar in shape, relatively small and ill defined. The cytoplasm showed basophilic staining and with the silver stain showed argentaffine granules. The nuclei were moderate in size, hyperchromatic and usually oval. Mitoses were rare. The microscopic diagnosis was carcinoma, unclassified.

The convalescence was uneventful except for the formation of a thoracic sinus, which discharged material from which *Staphylococcus albus* could be cultured. The patient was readmitted to the hospital in January and February 1934, at which times a two stage eight-rib posterior thoracoplasty was performed for the purpose of obliterating the space in the right hemithorax.

COMMENT

Not only has the patient remained free from metastatic disease, but all other patients surviving pneumonectomy for carcinoma of the lung in this series,⁴ with two exceptions, are still living and present no sign of recurrence. Only one patient surviving operation has subsequently died of metastasis, this occurring six months later. The other late death occurred from other causes a year after operation, and at postmortem

no trace of recurrent disease was found. In addition to the case reported, in which the five year mark has been passed, another patient in the series has lived four years and seven months, and two others will soon pass the three year mark. Furthermore, the loss of one lung has not placed limitations for the ordinary activities of life or the pursuit of happiness on any of the patients. This experience seems decidedly encouraging when it is realized that this form of cancer was practically a 100 per cent fatal disease before the accomplishment of surgical excision. Certainly, the fact that there are patients living today three, four and five years after treatment for primary lung cancer justifies the statement that the benefit of surgical aid be considered for all such patients if metastatic disease is not demonstrable at the time of clinical discovery of the primary lesion.

A CASE OF PURPURA HAEMORRHAGICA RESULTING FROM SEDORMID

HERMAN H. HUBER, M.D., MILWAUKEE

My purpose in writing this paper is simply to add another case to the growing list of cases of purpura haemorrhagica resulting from the ingestion of the drug "sedormid" (allyl-isopropyl-acetyl-carbamide). The interesting feature of the case described in this article is the fact that the patient was a physician and was able to observe the symptoms perhaps more analytically than a layman could. While confined to the hospital, he was shown an article by Loewy,¹ the first to appear in the literature discussing the ill effects following the use of sedormid. Since then forty-five cases have been reported.

REPORT OF CASE

A man aged 36, married, a physician, left on a trip west May 17, 1937. Desiring to assure himself of a good night's rest in the sleeper, he took one sedormid tablet (he had picked up a sample box in his office before he left) at about 10 p. m. At midnight he woke up with a severe chill, which lasted for more than an hour. At the conclusion of the chill his temperature was 102.5 F. and pulse 96. At about 8 a. m. the following day his temperature became normal and he decided to proceed on his way. After dinner he became nauseated and began to vomit. With it, vertigo developed. The vomiting was almost continuous and he decided to abandon his trip. At midnight he made the connection for the return trip. The following day the nausea continued but the vomiting subsided. He arrived home after midnight May 20 and vomited soon after arrival. When he was resting in bed the nausea and vomiting subsided. On examining himself he found a few purpuric spots over the ankles, knees and wrists. The purpura disappeared in a few days and he returned to work. August 7 of the same year was a very warm day and the patient, unable to fall asleep, took a sedormid tablet at 10 p. m. At midnight he was awakened by a severe chill, similar to the one he had had in May, lasting one hour. At this time an association was made with the previous chill and only then did it occur to him that both chills came on two hours after the ingestion of a sedormid tablet. Remembering then that purpuric spots appeared the previous time, he scrutinized his skin in the morning and found a few purpuric spots scattered over the entire body except for the face. Simultaneously on the pillow he observed spots of bloody saliva and on examination discovered that there was also bleeding from the gums. He pursued his usual duties, feeling fair except for a slight anorexia. The slow bleeding continued unabated and at midnight, at the request of his physician, he entered the hospital. The following day his entire body was covered with numerous purpuric spots of various sizes. Bleeding of the gums continued. The capillary fragility test was positive. The blood count showed secondary anemia. The bleeding time was ten minutes plus, the coagulation time two minutes. The spleen was not palpable. The platelet count was 40,000. Ascorbic acid and calcium were given. August 9 the

Fig. 2.—Appearance of chest five years and one month after right pneumonectomy. A two stage posterior thoracoplasty with the removal of long segments of the upper eight ribs was done for the purpose of obliterating the space in the right hemithorax.

urine became wine colored. August 10, the platelet count dropped to 20,000. The same day he received a transfusion of 500 cc. of blood. It was noticed that during the transfusion clotting was taking place rapidly, as he felt his teeth, which were covered with blood, sticking together. Bleeding from the gums stopped almost immediately before the transfusion was complete. No more purpuric spots appeared. The following day the platelet count rose to 100,000; the bleeding time was seven minutes. August 12, the platelet count was 110,000, and the bleeding time three minutes and forty-five seconds. The white blood cell count rose from 3,850 to 6,800. August 14 the platelet count was 150,000, the bleeding and coagulation times were normal and the patient left the hospital, returning to his duties August 23. By August 23, all the purpuric spots had disappeared. August 29 the platelet count was 170,000 and otherwise the blood picture was normal. November 6 the platelet count was 260,000. There had apparently been no bleeding from the gastrointestinal tract and there was no nausea or vomiting. The temperature, pulse and respiratory rates were normal during his stay in the hospital. The blood counts and platelet counts taken since then have been normal, the last one, taken March 23, 1939, showing white blood cells 6,950, platelet count 250,000, bleeding time one minute and forty-five seconds, differential normal.

COMMENT

It is noteworthy to state that the physician to the best of his knowledge had never been allergic to any foods or any drugs, although barbiturates had been taken in the past for

CONCLUSION

Further study of the drug sedormid and other potent sedatives which have crept into the armamentarium of the medical profession in such profusion during the last two decades should be made. Some of these drugs have unquestionably been a great boon to suffering humanity while others have been dangerous substitutes for the basic sedatives of the past.

EXPERIENCE WITH A RAPID CLINICAL TEST FOR
DIPHTHERIA (MANZULLA)

WAYNE W. FOX, M.D.; PAUL S. RHODES, M.D., AND
HERBERT LACK, M.D., EVANSTON, ILL.

In the Nov. 19, 1938, issue of the *Lancet* there appeared a summary of a report by Dr. Alfred Manzulla¹ of Buenos Aires concerning his experience with a rapid clinical test for diphtheria. The test was performed as follows: A cotton swab saturated with a 2 per cent aqueous solution of potassium tellurite² was applied to the suggestive exudate in the throat; after about ten minutes the area thus treated was inspected. Only those exudates due to infection with *Corynebacterium diphtheriae* turned black at the site of application of potassium tellurite. Manzulla found that in forty patients with throat exudate cultures of which showed *C. diphtheriae* the rapid tellurite test was positive in thirty-seven. Of thirty-five patients

Results of Tests for Diphtheria

Location and Character of Exudate	Clinical Diagnosis	Tellurite Test	Cultures
Both tonsils and uvula; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae
Left tonsil and uvula; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae
Right tonsil; pseudomembranous.....	? Diphtheria sore throat	Positive	C. diphtheriae
Both tonsils; follicular patchy gray; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae
Both tonsils; gray; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae
Both tonsils; gray; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae
Both tonsils; patchy gray; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae
Both tonsils and uvula; diffuse gray; pseudomembranous.....	Diphtheria sore throat	Positive	C. diphtheriae

Entire pharynx and larynx, requiring intubation.....	Diphtheria sore throat	Positive	C. diphtheriae
Left tonsil; gray, adherent membrane.....	Diphtheria sore throat	Positive	C. diphtheriae
Left tonsil; patchy gray; pseudomembranous.....	Streptococcus	Positive	No hemolytic streptococcus, no C. diphtheriae, no Vincent's angina
Right tonsil; small patch adherent, gray.....	? Diphtheria sore throat	Negative	No C. diphtheriae 6 times
Extensive membranous stomatitis.....	Vincent's angina	Negative	No C. diphtheriae, Vincent's angina ++
Pharyngitis, peritonsillar edema, soft gray pseudomembranous on uvula..	? Diphtheria sore throat	Negative	No C. diphtheriae, hemolytic streptococcus +
One tonsil, adherent gray pseudomembrane.....	Diphtheria sore throat	Negative	No C. diphtheriae, hemolytic streptococcus +
Left tonsil, adherent gray pseudomembrane.....	Diphtheria sore throat	Negative	No C. diphtheriae, hemolytic streptococcus +
Both tonsils and uvula, soft yellowish white exudate.....	Streptococcus	Negative	No C. diphtheriae, hemolytic streptococcus +
Both tonsils and uvula; white membrane, later stomatitis.....	Vincent's angina	Negative	No C. diphtheriae, no hemolytic streptococcus, Vincent's angina +
One tonsil; small patch yellowish exudate.....	Streptococcus	Negative	No C. diphtheriae, hemolytic streptococcus +
Post-tonsillectomy membrane, 2 days (diphtheria carrier preoperative)....	Diphtheria sore throat	Negative	No C. diphtheriae, no hemolytic streptococcus
No membranes or exudates (seven carriers).....	No disease	Negative	C. diphtheriae in all

occasional headaches or nervousness. As in the case cited by McGovern and Wright,² the patient suffered two distinct attacks following the ingestion of sedormid. Soon after the transfusion, hemorrhages in the various systems of the body subsided and apparent regeneration took place. The urinalysis was entirely negative two days after he left the hospital. It was fortunate that no hemorrhages occurred in the brain, where serious lesions might have occurred. While the amount taken in this case was comparatively small, the symptoms which supervened were unusually severe. The dosage may not be the important factor in this condition; the deleterious and permanent effects which might result from its uncontrolled use may be surmised.

2. McGovern, Teresa, and Wright, Irving: *Purpura Haemorrhagica Following Use of Sedormid*, J. A. M. A. 112: 1657 (April 29) 1939.

cultures of whose throat exudate showed no *C. diphtheriae*, none gave a positive tellurite test.

During the months of January and February 1939 this test has been applied to the exudate of twenty-seven patients with throat infections, seventeen of which yielded *C. diphtheriae* by culture on standard Loeffler's medium. In all these the potassium tellurite test was positive. There was one false positive tellurite test, in a patient having a unilateral, grayish, adherent

From the Department of Medicine, Northwestern University Medical School, and Cook County Contagious Disease Hospital.
1. Manzulla, Alfred: *Folia biol.*, May-August 1938, p. 355; abstr. *Lancet* 2: 1181 (Nov. 19) 1938.
2. One Gm. of potassium tellurite is dissolved in 50 cc. of distilled water at 40 C. The resulting solution is opalescent and on standing contains some grayish sediment. This should be suspended by shaking before use. A fresh solution must be prepared each month. With the minute amount used in the test there is no danger of toxic reactions.

tonsillar pseudomembrane, six cultures of which showed no *C. diphtheriae*. This patient denied the use of any gargles or lozenges. (Dr. Manzulla states that the use of peroxide gargles, tannic acid or methylene blue prior to the test may result in a false positive reaction.) There were nine patients whose cultures showed no *C. diphtheriae*, and all nine had negative tellurite tests. Of these nine patients, the etiology was hemolytic streptococcus in six and Vincent's *Fusiformis dentium* and spirilla in two. One patient, who had been a carrier for two months after an attack of pharyngeal diphtheria, gave a negative test two days after the performance of a tonsillectomy. Cultures taken this day and subsequently were negative for diphtheria.

Since we are unaware of any reports of the use of this test, either corroborating or disagreeing with the observations of Dr. Manzulla, we wish to present these results in the form of a preliminary report. A test which is so simple and rapid deserves careful study, particularly by physicians who see a large number of cases of acute throat infections. When the tellurite test is negative, it may be reasonably safe to withhold giving therapeutic antitoxin until the cultures are reported. With present rapid culture methods, this should involve no more delay than from twelve to eighteen hours.

636 Church Street.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—ED.

THE THERAPY OF CHRONIC ARTHRITIS

IN COLLABORATION WITH DR. EUGENE F. TRAUT

Chronic arthritis counts more victims than does tuberculosis. While not as fatal, it may be quite as disabling. Much better care for these unfortunates is demanded than has hitherto been their lot. The management of this disease requires superhygiene. "The arthritic must not only live well but better than well" (Pemberton).

There are three ways in which arthritis may be produced. One is from without (trauma or strain); another is from within (e. g., by infection). The third combines these two, the effect of strain on a joint damaged by disease resulting in a vicious circle. Other factors to the influence of which chronic arthritis owes its chronicity are endocrinopathies and subvitaminoses. Still more subtle is an inherited, constitutional inferiority of joint tissue. The therapy of chronic arthritis demands the breaking in on this vicious circle—the reason for its chronicity—at some point. One must treat the chronic arthritic patient as one with joint evidence of a systemic disease of probably multiple causation.

Chronic arthritis may be divided into two forms: specific and nonspecific. In the specific varieties it is assumed that the causal organism has been isolated or

the metabolic or mechanical causative agent has been recognized. A knowledge of the cause is the most rational lead to success in therapy.

INFECTION IN ARTHRITIS

Although the infections have arbitrarily been divided into systemic and focal, it is probable that most infections affect the joint focally by production of substances harmful to the joint in some area outside the joint. Diseases presenting a bacteremia are liable to metastasize to the joint, directly invading it. Probably any infectious agent may also act as a focus producing harmful substances, loosely called "toxins," which affect the hypersensitive joint tissues.

Tuberculosis in the latter sense produces "tuberculous rheumatism" and in the former a destructive arthritis with cold abscess. Tuberculous arthritis usually attacks a single joint or one joint at a time. Destruction of bone, cartilage and ligaments results in deformity; spindle-shaped "white swelling" may develop, as well as a "cold abscess," which may discharge through sinuses. The pain is seldom extreme and tenderness is localized rather than diffuse. X-ray examination reveals a distinctive arthritic involvement of the joint. Atypical forms of tuberculous rheumatism, though probably not common, are frequently unrecognized. This condition occurs especially in youngsters having foci of tuberculosis. It may involve many small joints. There may be serous effusion into a large joint. It has a protracted course.

Rheumatic fever (q. v.) has its own well known clinical characteristics. It must be admitted, however, that cases of borderline rheumatic fever exist which are difficult to classify. One should suspect chronic arthritis when the affected joint continues to be painful and the inflammation does not shift from joint to joint. Temperature, when elevated, is not as high as it is in rheumatic fever, and the pulse is likely to be more rapid. Lymph glands are much more likely to be affected. Rapid muscular atrophy, e. g. of the interossei, is suggestive of chronic arthritis; so are definite x-ray appearances of joint change and lack of response to salicylate.

Gonorrheal arthritis is frequently mono-articular. Pain is severe and especially marked at night. Swelling is very marked, there being usually quite a bit of synovitis. The finding of the gonorrheal focus and a positive complement fixation test make the diagnosis. In some instances gonococci can be isolated from the synovial fluid. Its prompt response to artificial fever and to sulfanilamide is suggestive.

Brucellosis should be borne in mind. Serologic and cutaneous tests may be necessary.

Focal Infection.—Whether one looks on more or less accessible tissues harboring pathogenic bacteria, now commonly regarded as focal or localized infections, as contributing substances directly injurious to joints or whether one regards them as detrimental to the patient's general health, and consequently as handicaps to his recovery from joint disease, one must agree that their elimination would be desirable. The profession is far more generally, if less enthusiastically, agreed on this principle. Although theoretically any part of the body may act as a focus, the foci of the alimentary tract (the teeth and rectum and less frequently the colon and gall-bladder), of the respiratory system (the tonsils, nasal

sinuses and bronchi), and of the urogenital tract (the prostate, cervix and tubes) are regarded as the more common. There are no indisputable criteria linking up tissue in one part of the body infected with such "nonspecific bacteria as streptococci, staphylococci or colon bacilli with disease elsewhere in the same individual. In particular, there exists no certain means of recognizing any two cultures of these bacteria as identical or as originating the one from another or the two from a common source. At present the treatment of one tissue as a focus of infection with the aim of aiding another part of the individual is justified only by the experience and judgment of the physician and the results of certain suggestive experiments.

Finding enlarged lymph glands may direct attention to the organ in the drainage area of the enlarged glands. 1. Diseased teeth are the most important foci in adults. The teeth must be examined roentgenologically and tested individually for vitality. Pulpless teeth should be extracted and pyorrheal pockets looked for. Absence of pain is of no significance. 2. The tonsils and adenoids are the most common foci of infection in children. But any patient with chronic arthritis with the characteristics of the infectious form deserves a tonsillectomy regardless of the appearance of the tonsils, provided other foci have been eliminated. 3. The nose, the ears and their adnexa the sinuses should be studied. This may demand a roentgenogram of the sinuses. Acute sinusitis is much less likely to act as a focus than the chronic form. 4. Infection of the bronchial mucosa, most especially bronchiectases, should be sought by roentgenograms, bronchoscopy and pneumography if cough is present. 5. The gastrointestinal tract must be explored for evidence of infection. Test meals may reveal hypochlorhydria or achlorhydria. Roentgenography may show cholecystitis (q. v.), colon stasis (q. v.) or colitis. The proctoscope may disclose colonic ulcers from which a culture may be obtained or from pus secured by duodenal tube; gallbladder drainage may show a preponderance of streptococci. 6. Urinary tract infection such as chronic pyelitis (q. v.) or cystitis (q. v.) should be looked for. 7. Pelvic infection should be suspected. The pelvic organs should be carefully palpated and the secretions expressed from the prostate, seminal vesicles and cervix, or the urethra should be examined for pus and bacteria.

REMOVAL OF FOCI OF INFECTION

Today the profession is much less enthusiastic, dogmatic and drastic in its attack on foci of infection. Certain it is that the time for their removal and the vigor with which they are attacked require considerable nicety of judgment. The patient must first be rested and built up. As previously stated, all apical abscesses or pulpless teeth require extraction. Pyorrhea (q. v.) pockets must receive thorough treatment. No halfway measures are admissible. If there is any doubt as to the condition of the tonsils, it is better to advise tonsillectomy. Nothing less than complete removal does any good, and this should include extirpation of adenoids if these are present. An infection of the nose, ears or sinuses, if present, demands a specialist's care and radical therapy if no other foci can be found. Digestive abnormalities must be corrected not only for the sake of removal of possible foci of infection but also to improve general nutrition, on which, after all, ultimate

recovery depends. Any abnormality of the genito-urinary tract requires equally radical and determined treatment.

Even when the operative procedure is undertaken after the patient's resistance has been improved, so far as can be, a temporary exacerbation of the arthritic process may result. It is well to warn the patient of this possibility. One may also say that this exacerbation, should it occur, might be taken as a welcome token that the cause of the disease is being attacked.

IMPROVING RESISTANCE

We know that all infection has a natural tendency to recovery. Were there a single infection from which recovery is impossible, humanity would have long since been exterminated by that infection. Hence in all cases of chronic arthritis the physician must discover the reason for the persistence of the infection. This is always due to poor resistance, which may be local or systemic; the latter may be hereditary or acquired. It is generally poor local resistance that determines the presence of foci of infection, and this is the reason such foci demand extermination.

The patient's systemic resistance requires building up. The patient's food habits demand investigation, particularly as to his vitamin intake, for subvitaminosis lessens resistance and infectious states per se demand an increased vitamin intake for expeditious recovery. The diet should, in general, be low in carbohydrates, especially as to the concentrated, refined carbohydrates such as white flour, corn starch, rice and sugar. The caloric requirements can be met with fats if the patient is emaciated. Constipation and obesity demand diets with a high cellulose content to provide bulk as a peristalsis stimulant and to replace the hunger satisfying effect of foods of higher caloric value. Patients with a history of "irritable bowel," "colitis" or tendencies to colonic distress and loose stools require expert regulation of the cellulose intake. The amount of roughage must be adjusted to their tolerance. In patients with carbohydrate indigestion one must rely on fats to furnish diets of sufficiently high caloric value. Protein is advised in twenty-four hour amounts of not less than 1 Gm. per kilogram of body weight in any case. This amount is increased without hesitation in anemic patients as well as in patients with the occasionally complicating nephrosis, in patients with low metabolic rates and in the obese. Anemic patients and also obese patients should be given lean meat in 100 Gm. quantities as often as twice a day, and eggs with their breakfast. The vitamin and mineral content of the diet must be as high as possible, even to the inclusion of cod liver oil, brewers' yeast and calcium compounds. Iron therapy is prescribed liberally to correct the secondary anemia (q. v.). Diluted hydrochloric acid in amounts up to 6 cc. is given with each meal to patients with achlorhydria or hypochlorhydria. Arthritic patients with hypothyroidism are given whole thyroid up to tolerance. This is likely to be particularly indicated in women at the menopause.

Heliotherapy is just as beneficial in increasing the resistance in the arthritic as it is in the tuberculous. Living and sleeping outdoors is therefore ideal, provided the patient is not chilled and that he is carefully protected against sudden changes of temperature. Warm socks and gloves are of comfort. Change of climate

from the North to the South in winter is advisable whenever this is possible. Ultraviolet rays increase resistance if used generally and may relieve pain when applied locally.

Parenteral alterative therapy makes use of relatively heroic appeals to the patient's powers of resistance that are a tax on the system's resources. Hence this form of therapy should be resorted to only when the patient's nutrition has been improved as much as possible. It must never be attempted during an acute exacerbation, in the ill nourished or in the organically handicapped. The intravenous injection of salicylate, of iodide or of colloidal sulfur may be considered examples of this treatment. Autohemotherapy, one of its mildest forms, has been found helpful in gonorrheal arthritis. It consists of injecting 2 cc. of the patient's blood (which is secured by venipuncture) into the buttock, and increasing the dose by 2 cc. every third day until such reaction as increase of pains or fever occurs. At the other extreme of potency stands the intravenous injection of typhoid vaccine—starting with 50 million bacilli and increasing every fifth day to 150 million or more as required to secure a pronounced febrile reaction. Stock or autogenous vaccines may or may not be of value. In subacute gonorrheal arthritis the filtrate of autolyzed gonococci (Herrold) injected in sufficient dosage to cause chill and fever has been useful. Pyrexial therapy is specific for gonorrheal arthritis, possibly because of the thermolability of the gonococcus. It may be of some value in other forms of chronic arthritis.

NONINFECTIOUS SPECIFIC ARTHRITIS

Gout (q. v.) is relatively rare in its classic form. In early cases marked joint changes are absent. The finding of tophi is characteristic. The finding of an increase of blood uric acid without simultaneous excess in blood urea is suggestive. Characteristic are sudden recurrent attacks after excesses in food, alcohol or exertion, as well as sudden relief of the excruciating pain at the end of the attack. Gout gives a specific response to correct therapy. Gout is the only type of arthritis relieved by colchicum.

Allergy, and especially food allergy, may account for some cases of chronic arthritis. Certain it is that in some a sharp fast will usher in a period of convalescence better than any other therapy. There are some patients who believe that some kinds of foods are liable to provoke recurrence of attacks. In the treatment of all arthritic patients of the dietetic type the broad principle must not be forgotten that "optimal" nutrition is the sine qua non for maintaining resistance and that, if any elimination of important dietary ingredients seems indicated, this should be balanced by other food of similar composition that is found to agree with the patient.

It is indeed possible that allergy plays a greater role in chronic arthritis than is commonly realized. All the aseptic inflammations so characteristic of chronic arthritis may possibly be "allergic" in nature because of specific hypersensitiveness. It may be the joint response of systemic sensitization to tuberculin or to the metabolic products of other bacteria. That allergy may cause arthritis is shown by the joint swellings and inflammations occurring in serum disease. There is no doubt that some cases, at least, of intermittent hydrarthrosis are due to hypersensitivity.

Charcot's joint may also be included under this heading. The presence of Charcot's joint should be detected by general examination of the nervous system for tabes dorsalis or syringomyelia, and its recognition should protect the patient against having his lightning pains treated as "muscular rheumatism." Charcot's joint is at present regarded as a form of traumatic arthritis due to misuse of joints because of loss of deep sensibility.

NONSPECIFIC THERAPY

When a specifically manageable cause cannot be discovered and indeed also when it can be but requires time for its cure or is incurable, nonspecific therapy comes to the fore.

An abundance of rest in bed should be prescribed and its degree specified. This may vary from absolute rest in bed during acute phases of the disease to relative rest, e. g. an hour in bed in the middle of the morning with a nap directly after lunch or in the middle of the afternoon. All patients are advised to spend at least ten hours in bed at night.

Physical therapy is much more important in chronic arthritis than is medicinal therapy. In the acute stages rest and heat are indicated, while such evil effects of rest as weakening of the muscles and stiffening of the joints must be antagonized by appropriate massage and active exercises.

Local rest is demanded by any acute exacerbation of chronic arthritis and by local disease, whether this is due to trauma (sprain or strain) or from occupation (e. g. "air-hammer elbow"), relaxation of the ligaments (sacro-iliac), flat foot, bursitis (q. v.) or neuritis (q. v.). When the patient has sufficiently recovered to return to work, trauma and strain incident to his occupation must be discovered and removed, especially for joints handicapped by previous disease.

Production of hyperemia is of value for antibacterial, analgesic, reparative and resorptive effects. Thus heat is employed to relieve pain and stiffness, to induce relaxation before massage and to encourage certain poorly understood, favorable metabolic processes in the affected part. Acutely inflamed joints should be exposed for an hour or two daily to a cradle containing four electric light bulbs, screened so that the patient cannot burn himself, or be wrapped in hot voluminous dressings of half-saturated solution of magnesium sulfate. A convenient method of the application of heat is the hot paraffin film. This is applied by melting (low melting point 150 F.) paraffin and, when it is just at the congealing point, coating the affected part by dipping it in and then withdrawing it or by painting the melted paraffin on the surface until several layers have been applied. The film is left on for three quarters of an hour or until it comes off easily. In the subacute and chronic types these forms of the application of heat should be dictated by the demand for the relief of pain; counterirritation should be employed to improve the local circulatory activity, as by painting the affected joint with tincture of iodine, applying small cantharides plasters to persistently tender points or "baking" the limb for from twenty to thirty minutes once a day in severe cases ranging down to two or three times a week in others. Short wave or classic diathermy several times a week is of similar value. The local use of ultraviolet rays may also be mentioned here.

Retentive appliances are important. The prevention of deformity is much easier than its cure. It demands persistent efforts to antagonize contractures. The affected joints should be put up in light, well padded splints for several hours a day and especially over night. Prolonged immobilization by encircling plaster of paris casts is contraindicated. One may, however, use pelvic and/or leg traction and night splints (posterior molds, either metal or plaster), from which the limbs can be removed for other physical therapy. Removable splints are likewise useful for the maintenance of the foot at right angles, with neither inversion nor eversion, and for the wrists cock-up splints extending to the proximal palmar crease. For cases in which the back is involved a relatively firm bed is needed for recumbence or a posterior plaster shell supporting the drooping ribs when necessary and a proper corset or brace for ambulation, if prolonged bed rest of aged patients can be avoided thereby. In all arthritic cases the lifting of weights and all straining must be carefully forbidden for a long time.

Mobilization therapy should be instituted in atrophic arthritis as early as possible. It is especially indicated in cases presenting periarticular involvement. In the hypertrophic form all kinds of early manipulation are contraindicated. This is also true of Heberden's nodes, which must not be rubbed and should be protected against occupational trauma.

Massage should always be preceded by hyperemia (e. g. heat) and followed by rest. When a joint is acutely painful either it should not be massaged at all or the lightest stroking only should be applied to the parts above and below the joint (introductory massage). As soon as the pain is no longer severe, gentle friction (circular movement) and kneading should be applied. The muscles above and below the joint may now be given more vigorous treatment. As tenderness disappears the joint itself may be treated more energetically; but this must never be to the extent of inflicting pain. The patient may be taught to massage himself, or members of the family may be trained to massage the part. Light active movements are allowable as soon as they are not accompanied or followed by pain. This statement may seem to be irreconcilable with the primary indication for rest of all acutely inflamed joints. It should be understood, however, that it is friction of joint surfaces, the overcoming of resistance and the bearing of weight that is destructive to diseased cartilage and productive of hypertrophic changes. By exerting traction and separating as much as possible the surfaces of the affected joint, a certain amount of slight movement may often be effected without producing pain or harm. The aim of the exercises is to prevent adhesions and contractures, which often develop with great rapidity.

Exercise is encouraged up to the patient's tolerance. Marked fatigue or pain lasting into the next day is a sign that his disease-instituted limits have been exceeded. The patient is taught exercises especially adapted to the joints involved. Movements are often possible in warm water that are impossible out of it. The majority of patients are improved by the performance of such postural exercises as those of Goldthwaite and Osgood. These exercises should be taught and frequently

rehearsed. Typewritten instructions and record sheets should be employed to individualize better the patient's therapy. Purposeful movements, exercise in making something (occupational therapy), are especially helpful in securing movement of particular groups of joints. They should be devised and taught by occupation therapists after advising with the attending physician. This occupational therapy should also be developed in the direction of possibly teaching the patient a new means of earning his living, for, as in the case of tuberculosis, a return to the patient's previous mode of living often means the return of his disease.

Surgery may be required after careful study of the x-ray film to determine the degree of damage present in the articular surfaces. Only when the joint disease is quiescent may tenotomy, capsulotomy, synovectomy or arthroplasty be indicated. Bony exostoses limiting joint movement may have to be removed and contracted tendons divided to straighten a crooked joint. In villous arthritis the removal of the hypertrophied fringes may result in great relief and improvement of function. After operation, joints must not be left in plaster casts for long unless ankylosis is sought.

As to medicinal treatment, besides the previously discussed restoratives (iron, hormones, vitamins) as required by the patient's deficiencies, analgesics may be demanded. Among these acetylsalicylic acid in doses of 0.3 Gm. (tablets) every two to four hours or even oftener may well be first choice. If too severe diaphoresis is produced before relief is secured, the addition of extract of hyoscyamus (0.02 Gm. per dose) may be of value. If pain is not sufficiently relieved or if it interferes with sleep, the addition of phenobarbital (0.05 Gm.) is advisable. Codeine phosphate (0.05 Gm.) should be added only if relief cannot be obtained without it. A course of arsenic therapy may possibly render service.

SUMMARY

To be successful in chronic arthritis the proper treatment must be started early and continued over a long time. Too commonly the diagnosis of "rheumatism" is made and everything that is prescribed in consequence (keeping the patient indoors, the prolonged use of heat, a protein diet, large doses of salicylate) does more harm than good. The treatment should be more nearly like the general regimen of tuberculosis. The patient's whole mode of living needs to be changed.

CONCLUSIONS

From these considerations the following conclusions are obvious:

1. Cook County Hospital, because of the great demand made on it for beds in which to take care of acute disease, should accept patients with chronic arthritis only for a general assay of the patient's condition to determine the best means of attacking the disease, to follow this with education of the patient and of his family and to perform any required surgical procedure.

2. A separate section of Cook County Hospital, a properly equipped "convalescents' hospital" or else a special institution for arthritic patients should provide for the care and study of the majority of these patients.

Such an institution would do a great deal to advance our knowledge of the rheumatic diseases and their cure.

3. After the patient has improved sufficiently to be permitted to go home, he should be kept under the supervision of an "arthritis clinic," which by prompt and appropriate treatment may succeed in keeping the patient from again becoming an inmate of the institution.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

KETOCHOL NOT ACCEPTABLE FOR N. N. R.

Ketochol, which is stated to be "a combination of the oxidized, or keto, form of the bile acid (cholic, desoxycholic, chenodesoxycholic and lithocholic) normally present in human bile," is advertised extensively to physicians by G. D. Searle & Co. According to an advertising circular it is proposed for use in the "treatment of chronic cholecystitis, cholangitis, hepatic dysfunction, congestion and cirrhosis." No chemical examination of the product has been made but it is believed that the mixture is composed largely of dehydrocholic acid.

COMMENTS ON THE PAMPHLET ENTITLED "STEPS UPWARD"

The statement "Ketochol offers a combination of the oxidized, or keto forms, of the bile acids (cholic, desoxycholic, chenodesoxycholic and lithocholic) in approximately the same proportions as in normal human bile" is misleading. It has not been shown that these keto acids occur in human bile in any amount and very little information of quantitative character is available about the proportions of the unoxidized compounds. Further, the bile acids are not present naturally in bile as either free acids or sodium salts but as conjugation products with either glycine or taurine.

The statement "Ketochol is effective in the treatment of chronic cholecystitis, cholangitis, hepatic dysfunction, congestion and cirrhosis" is, of course, unwarranted. The statement in the same paragraph "By improving liver function it assists in combating intoxication and in detoxifying the blood stream" is likewise unwarranted, since there is no evidence that such keto bile acids do improve liver function. As a matter of fact there is reason to believe that they act on the liver as a toxic substance which is rapidly eliminated in the bile as such. They do not cause an increased secretion of solids but rather the production of a copious watery bile in which keto acid is eliminated unconjugated.

COMMENTS ON THE PAMPHLET ENTITLED "A PHYSIOLOGIC CHOLECYSTOTOMY"

The statement that "Ketochol is a combination of oxidized, or keto form of the bile acids . . . normally present in human bile" is objectionable on the grounds already stated. Also the statement under "Indications" that the mixture "is effective in the treatment of HEPATIC DYSFUNCTION" is altogether too broad and meaningless. It might be wise also to include the contraindications to this medication.

COMMENTS ON THE PAMPHLET ENTITLED "THE NEW TREATMENT OF GALL BLADDER CONDITIONS"

Objection is made to the statement on the last page: "Ketochol, developed in the Searle Research Laboratories, offers a combination of the oxidized, or keto form, of the bile acids (cholic, desoxycholic, chenodesoxycholic and lithocholic) normally present in the human bile" and to the recommendation in the next paragraph that "Ketochol stimulates liver function." Also objectionable is the statement that Ketochol is most effective in the treatment of "hepatic dysfunction and congestion."

In view of the foregoing report, the Council declared Ketochol not acceptable for inclusion in New and Nonofficial Remedies, and authorized publication of this statement.

Council on Foods

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

ANNUAL MEETING OF THE COUNCIL ON FOODS

The annual meeting of the Council on Foods, held at the Association headquarters on March 18, was attended by the following members:

Dr. Franklin C. Bing	Dr. James S. McLester
Dr. George R. Cowgill	Dr. Irvine McQuarrie
Dr. Morris Fishbein	Dr. Lydia J. Roberts
Dr. Philip C. Jeans	Dr. Mary Swartz Rose
Mr. Culver S. Ladd	Dr. Tom D. Spies
Dr. Howard B. Lewis	Dr. Russell M. Wilder

For all or part of the meeting there were also present the following members of the Council on Pharmacy and Chemistry:

Dr. P. N. Leech	Dr. E. L. Severinghaus
Dr. E. M. Nelson	

Also in attendance were Mr. Howard A. Carter, secretary of the Council on Physical Therapy, and Dr. Harold L. Hansen, secretary of the Council on Dental Therapeutics of the American Dental Association.

Drs. Fishbein and Lewis were reelected Chairman and Vice Chairman of the Council, respectively. Physicians, manufacturers and others may be interested in the following topics which were among those given consideration at the meeting:

Scope and Significance of the Seal of Acceptance.—It has not been possible for the Council to exercise supervision over foods of every kind; hence certain natural foods of well known nutritive value, such as milk, butter, eggs, fresh fruits and vegetables, are not accepted, although claims made in general advertising may be reviewed and given the seal of acceptance. Any misunderstanding of the Council's position is regrettable. Processed foods have been the chief concern because it is largely through advertising that the consumer is informed as to the composition and nutritive properties of such foods. The Council aims to render service by recognizing the products of firms which honestly desire to restrict their claims to those which the Council believes are well established.

The appearance of the seal on fabricated foods does not indicate that such products are to be preferred over nutritionally desirable products in their natural state. All foods which stand accepted are considered by the Council to be wholesome but not necessarily to be preferred to simple natural foods.

Questions pertaining to the significance of the seal are perennial. A subcommittee, appointed to study the problem, presented a report and offered a number of suggestions. It was thought that the seal might well be modified to provide some explanation of the significance of the word "Accepted," about which much of the difficulty revolves. The committee suggested that the statement be modified to read "Accepted as Represented." It also was suggested that, when the seal is used in advertising, it might be well to require that it be accompanied by an appropriate statement such as "This seal signifies that the statements and claims made in this advertising conform to the standards of the Council on Foods of the American Medical Association." The committee's report called attention to the activities of various trade groups, notably some members of the ice cream industry, who have sought to establish high standards of nutritional and sanitary qualities of their products. The Council views most favorably progressive steps on the part of the food industry. It was suggested that the seal might well appear on the advertising of such trade organizations with a statement to the effect that "This seal signifies that the Council on Foods of the American Medical Association believes the standards of quality established by our organization are in the interest of public health. The maintenance of these standards is the responsibility of this firm." There was considerable discussion of each

of these proposals, but no action was taken pending a further report of the committee after the book "Accepted Foods" has been completed.

The Book "Accepted Foods."—There are twelve sections to the book and all but four have been completely written. Work is progressing on the remaining material and the book should be available within a few months.

Fortification of Foods with Vitamins and Minerals.—Further consideration was given to the recommendations of the Cooperative Committee on Vitamins, which have been published recently (*THE JOURNAL*, August 12, p. 589). After considerable discussion it was decided that mild fortification of cereal products with calcium or iron salts or both might well be recognized. The fortification of cereals with vitamin D was again given consideration and it was decided that such manipulation of cereals could not be recognized because it did not seem to be in the interest of public health, at least on the basis of present information. A further report on the desirability of adding vitamin B₁ to cereal products is being prepared for publication. As a result of its study of available evidence, the Council adopted the following statements as an expression of present policy:

The Council on Foods desires to encourage the restorative addition of vitamins or minerals or other dietary essentials, in such amounts as will raise the content of vitamin or mineral or other dietary essential of general purpose foods to recognized high natural levels; with the provision that such additions are to be limited to vitamins or minerals or other dietary essentials, for which a wider distribution is considered by the Council to be in the interest of the public health.

The Council is opposed to the indiscriminate fortification of general purpose foods with vitamins or minerals or other dietary essentials. By fortification is meant the addition to a food of such an amount of a vitamin or other dietary essential as to make the total content larger than that contained in any natural (unprocessed) food of its class.

The following fortifications are recognized by the Council as being in the interest of the public health: (1) the addition of vitamin D to milk to an extent not to exceed 400 units per quart, no objection being made when the added vitamin is obtained from a natural source, if it carries with it one or more other vitamins; (2) the addition of vitamin A to substitutes for butter to an extent not to exceed the amount of vitamin A in butter of high natural content of vitamin A, no objection being made when the added vitamin is obtained from a natural source, if it carries with it one or more other vitamins; (3) the addition of iodine to table salt in an amount not to exceed one part of sodium or potassium iodide for each 5,000 parts of salt; (4) the addition of calcium salts to wheat flour or other cereal product in an amount such that the calcium content of the finished product does not exceed 0.075 Gm. for each 100 calories, and (5) the addition of iron to wheat flour or other cereal product in an amount such that the iron content of the finished product does not exceed 0.0015 Gm. (1.5 mg.) for each 100 calories.

Lead in Foods.—It must be apparent to readers that the Council has been concerned with the problem of lead in foods for some time (*THE JOURNAL*, May 29, 1937, p. 1890; July 9, 1938, p. 154). A progress report was made of present investigations under a special grant for research provided by the Board of Trustees, and a full report of this work will be published later.

Consideration was given to a recent development of the apple industry, whereby culls are converted into a beverage. In some instances the apples are crushed without removal of the skins and cores and the macerated fruit is evaporated under diminished pressure, resulting in the preparation of a fragrant apple syrup having a high concentration of levulose. Such products, of course, ordinarily are diluted before use, but they are sold in the concentrated form. The concentrated juice presents a problem when the content of spray residues such as lead or arsenic or both exceeds the tolerances for these elements, even though after dilution the beverage may be considered satisfactory. The Council voted not to accept these apple products unless in the form in which they are marketed they contain less than two parts of lead (as Pb) and 1.06 parts of arsenic (as As) per million.

Fluorine in Foods.—Within recent years certain insecticides containing fluorine have been introduced in agriculture. The Food and Drug Administration of the U. S. Department of Agriculture has established a tolerance of the amount of fluorine that will be permitted on fruits when sprayed with insecticides containing this element. The present tolerance is 0.02 grain per pound, which is equivalent to 2.8 parts per million. In the opinion of the Council, it is proper that a tolerance for fluorine should be established for fruits on which insecticides containing compounds of this element have been used. Fluorine is known to be toxic in large amounts and, in smaller amounts, to exert a deleterious effect on teeth and bones.

The question was raised about the attitude of the Council toward the use of ground bone or bone meal in cereal preparations, particularly those intended for the feeding of infants. Dried powdered bone long has been used as a source of calcium and phosphorus in the preparation of feeds for farm animals, and a number of years ago rock phosphate was introduced as a substitute. The use of the latter led to disastrous results which were found, after extensive investigation, to be caused by the relatively high amount of calcium fluoride in most rock phosphates. Animals fed on foods containing high amounts of fluorides developed abnormalities of the bones and teeth. The human being also is susceptible to fluorosis. The teeth are affected in young children living in districts where endemic mottled enamel occurs. The only studies of tooth changes in children that have been reported have been in relation to water supplies. It has been shown that fluorine in water up to about 0.8 part per million has no noticeable effect on teeth, but mild mottling may occur above this level and, with concentrations of six or more parts per million, severe pitting and chipping of the enamel may result. Several investigators have agreed that the maximum nontoxic limit for fluorine in water is about 0.8 to one part per million, when mottled enamel is used as the criterion. If one estimates that the infant may consume about 300 to 400 cc. daily of water, the intake will be about 0.24 to 0.32 mg. of fluorine daily if the water contains 0.8 part per million. In the case of cereal preparations fortified with bone meal (to supply additional calcium and phosphorus), the maximum serving for a child would rarely be greater than about one ounce. On the basis of a fluorine content of ten parts per million (practically all of which is derived from the ground bone) one ounce of such a cereal mixture would contain about 0.28 mg. of fluorine or about the same as the intake of fluorine from water containing the maximum nontoxic level of fluorine.

In discussing the question, it was brought out that the relative availability of fluorine from different sources must be considered. The fluorine in water supplies is present as the fluoride ion, which is readily absorbed. The fluorine of bone is largely present as calcium fluoride, which is insoluble and poorly absorbed, as has been reported by several investigators working independently. The evidence indicates that fluorine as a natural component of food is nontoxic, even though the amount present might exceed that usually considered toxic under certain circumstances.

There is even some evidence that small amounts of fluorine may contribute to human well being, although this is by no means established. It is known, however, that carious teeth contain considerably smaller amounts of fluorine than are found in sound teeth. A recent report calls attention to a greater immunity to dental caries in children residing in communities where the fluorine content of the water is comparatively high. Further investigation of these interesting topics may prove most fruitful.

On the basis of available evidence, the Council sees no reason why bone meal should not continue to be accepted as a satisfactory ingredient of cereal mixtures intended for the feeding of infants, although it would be highly desirable to select bone that is relatively low in fluoride. There is a remote possibility that, in regions where the fluoride content of the water is somewhat near the point of toxicity, other sources of fluorine such as those provided by foods might assume unusual importance. As a guide to physicians and others interested in the problem, the Council voted to request additional information about the fluorine content of cereal products specially designed for infant feeding, with the view to including the information in the book of Accepted Foods.

ASSOCIATED HOSPITAL SERVICE OF NEW YORK REVISES ITS CONTRACTS

What happens when arrangements are made to provide medical and hospital services on an insurance basis without sufficient actuarial data is clearly told in a news release from the Associated Hospital Service of New York. The new agreement which the Associated Hospital Service is making with its subscribers is based on a study of the four years experience of the service; it embodies several new limitations and some liberalizations of the former contracts.

About 57,000 contracts with subscribers who enrolled through individual instead of organized group applications are to be terminated. This was announced recently as a result of this study, which indicated that under past enrolment procedures a proper distribution of risk was not provided.

Three types of contracts are to be issued: one for individuals, one for husband and wife, and one for a family group consisting of husband, wife and all unmarried children less than 18 years of age. This third contract will include maternity benefits. The husband and wife contract will be issued at a rate equal to double that paid for an individual member. This is said to be the only change in rates. Husband and wife who desire maternity service benefits may join the family plan; however, subscribers who enroll under the family contract other than through organized groups will not receive maternity benefits. Although the news release does not call attention to this limitation as a further means of providing a more equitable distribution of risk, this limitation does mean that the maternity benefits can be obtained only through enrolment in organized groups.

If the subscriber has been a member of the plan for six months, hospital service for the removal of tonsils or adenoids will be provided. One day of care will be offered to patients less than 12 years of age, and two days of care will be provided for those who are over 12 years of age. Thus, it will be observed that

persons who require hospital service for the removal of tonsils or adenoids must be prepared to leave the hospital in one or two days. The matter of complications is apparently at the patient's own expense.

Under the new agreement, the plan will not cover the following illnesses and services: pulmonary tuberculosis after a diagnosis has been made; communicable diseases, such as scarlet fever which requires isolation; smallpox, diphtheria, venereal diseases, etc. No explanation is made of the "etc." Functional, nervous and mental diseases and congenital disorders are not included among the benefits. No provision is to be made for radium and x-ray treatments or physical therapy. Special medications, oxygen, vaccines and blood for transfusions are not to be provided, and patients are to be denied proprietary medicines. There will be no provision for outpatient and emergency treatment, ambulance service, admissions primarily for diagnosis, and conditions provided for under workmen's compensation, veteran's compensation or any similar conditions for which medical and hospital care is provided by existing laws. It is stated that the plan will not pay the subscriber's doctor bill or the cost of the services of private nurses.

Shortly after the organization of the Associated Hospital Service of New York, it was announced that the hospitals had agreed to accept subscribers to the plan at a minimum rate of \$6 a day, but it was contended at that time that the prospects were good that this rate would be increased in the future to \$7 or \$8 a day. Although the amount paid to hospitals for general services is not given in the news release, it is stated that a credit of \$5 a day for a period of ten days will be granted to maternity cases after the subscriber has been enrolled for eleven months.

It is admitted that nonprofit group insurance against the cost of hospital care is new and has no working principle. It is further stated that patients who take undue advantage of the benefits offered by the service are being unfair to other subscribers. In the future an attempt will be made to limit the stay in a hospital on the basis of the physician's recommendation and it seems to be the policy to require those patients who desire to remain in the hospital a longer time than is necessary to pay the additional cost.

Definite comment is not made on the increased demand for hospital service due to epidemics or other unpredictable medical conditions or to the natural increase in demand which comes from hospital mindedness, which is an ultimate and natural outcome of an insurance arrangement. However, it is stated that a limit has been placed on the credit of \$25 which is provided for the use of the operating room, \$25 credit for x-ray and \$20 for laboratory examinations, to prevent excessive and unnecessary demands.

It is claimed that the revisions in the agreement with subscribers are normal and were to be expected. Furthermore, it is stated "and as our knowledge of

the incidence of sickness in the enrolled groups and the cost of its care is increased, changes in the contract have been made in the light of such experience in order to stabilize its provisions."

No comment is made as to the reaction which is likely to follow from the cancellation of contracts. The reader of the news release is left with the impression that with these revisions the service is now on a perfectly sound actuarial basis. This is the impression that was given at the beginning of the plan and that has been announced from time to time until comparatively recently. Perhaps another four years experience will indicate some additional changes in the contracts.

VITAMIN B₆

The development of knowledge concerning the vitamins includes striking examples of the application of the results of experimental investigation to clinical medicine. In many instances the routine clinical use of the vitamin has preceded definite information regarding its chemical constitution. The use of concentrates has been of great practical benefit. The point is admirably illustrated by our present knowledge of the vitamins of the B group or the so-called vitamin B complex. The early history of vitamin B demonstrated that this factor had profound effects on growth, gastrointestinal motility, appetite, carbohydrate metabolism, integration of nerve action and other physiologic processes and functions. These observations led to a search for individual substances as members of the B group of vitamins. The chemical nature of vitamin B₁ and of vitamin B₂, or G, has now been established and confirmed by synthesis, as has also the structure of the antipellagra substance nicotinic acid, also a member of the vitamin B complex. Although these vitamins were being used in the form of concentrates before their chemical identification, their clinical value has been enhanced and expanded by the availability of the synthetic products.

To the vitamins of the B group which are known in chemically pure and in synthetic form, namely thiamin (B₁), riboflavin (B₂ or G) and nicotinic acid, must now be added a fourth member, the factor termed vitamin B₆. At least six B vitamins have been proposed. Other "factors," with a variety of nomenclatures and functions, have also been proposed for inclusion in the B group of vitamins. There is some uniformity of opinion in the use of the term vitamin B₆, which has been applied to that factor of the vitamin B complex which prevents or cures an acrodynia-like dermatitis in young rats.¹ It has also been stated² that puppies on a vitamin B₆ deficient diet develop a severe microcytic hypochromic anemia, which is cured by the addition of this factor to the diet. The structure of vitamin B₆ has

been recently established independently by laboratories³ in Germany and in this country, and the American investigators⁴ have also reported a complete synthesis of the vitamin as conclusive support for the proposed structure.

One of the most interesting of the developments in the chemistry of vitamin B₆ is the demonstration that the substance is a derivative of the nitrogenous base pyridine, being a methyl, hydroxy, dihydroxymethyl substituted pyridine. The base pyridine is also the fundamental ring structure in nicotinic acid, and the amide of the latter compound is a component of the enzymes comprising the dehydrogenase group. The importance of the pyridine nucleus already established in biologic oxidations and reductions appears to indicate that certain functions of vitamin B may be concerned with similar types of biologic reactions. Indeed, Birch⁵ has recently suggested that the physiologic function of vitamin B₆ is connected with the utilization of the unsaturated fatty acids.

The availability of synthetic vitamin B₆ will no doubt greatly stimulate experimental efforts to elucidate new information regarding its physiologic functions. Furthermore, if the pharmacologic properties of the vitamin permit, possible therapeutic functions of this new compound should be explored. Indeed, a very recent account⁶ describes the striking improvement in muscular and neurologic symptoms in four persons who were given 50 mg. of synthetic vitamin B₆.

Current Comment

FUNCTIONAL CAPACITY OF THE UNDESCENDED TESTIS

After reviewing the literature on the incidence, causes, microscopic appearance and treatment of the undescended testis, Rea¹ concludes that the undescended testis has an internal secretion. The evidence for its external secretion of viable spermatozoa, however, is scanty, and it is toward this question that his attention was given. For the experimental study of this problem only naturally cryptorchid animals, chiefly the dog and the pig, were used. Smears were made from cut sections from the testis, epididymis, vas deferens and seminal vesicles of abdominal testes in eleven full grown pigs. Microscopic sections also were made from these organs, and both smears and sections were searched for spermatozoa and the germinal epithelium was scrutinized. Although the gonads in each case showed the usual degenerative changes, smears made from cut sections of the testis revealed spermatozoa in six. As a result of other carefully devised

and executed studies of descended and undescended testes in man and animals, the author concluded that the undescended testis does not differ grossly or microscopically from the normal up to puberty but after this undergoes degenerative changes. How long the undescended human testis remains capable of function is unknown. There are undoubtedly cases in which spermatogenesis has persisted into adult life. It may be estimated that 10 per cent of untreated human cryptorchids remain fertile. Since it has been proved clinically that as high as 82 per cent of those treated by orchiopexy have active spermatozoa in the semen, this procedure may be considered generally desirable. Judging from the number of spermatozoa in the ejaculated semen, as well as in the microscopic appearance of the undescended testis after orchiopexy, such organs probably never attain an approximately normal functional capacity. It is not known whether the potential function of the ectopic testis is inherently smaller than that of the descended gland. The results of microscopic examination up to the time of puberty and the results of tissue culture fail to show any positive proof of congenital imperfection. Most imperfections become apparent at puberty, probably as a result of the influence of the hormonal and of extrinsic anatomic factors arising at that time.

STILLBIRTHS AND NEONATAL DEATHS IN FAMILIES

Some families seem to be excessively susceptible to stillbirths and deaths in early infancy. The statistical difficulties in the establishment of this impression as a fact are numerous because of such complicating factors as the external environment, the age of the mother, the prematurity of the infant and the widespread reduction in the number of pregnancies of individual women. Elizabeth Gardiner and Yerushalmy¹ have made an excellent attempt at the statistical study of this problem by analyzing all the births other than first births that occurred in 1936 in New York State exclusive of New York City. The statistical method used attempted to allow for the complicating factors mentioned. The investigators found that neonatal mortality as well as the stillbirth rates of infants born to mothers who had had previously one or more infant losses was more than twice that of infants born to mothers who had previously had no such losses. Furthermore the increasing mortality varied directly with the number of previous infant losses. Thus infants born to mothers who had had four or more previous losses were exposed to a risk of stillbirth and neonatal mortality more than four times as great as that of infants whose mothers had had no previous infant loss. This increased mortality associated with previous infant loss was found to be present in every order of birth and was extremely pronounced in the case of second births. The increased mortality was considerable for every age of mother, although the difference in rates was greater among infants of young than of old mothers. They also found that the frequency of premature birth to mothers who had had previously an infant loss was much higher than that of infants born to mothers who had not had such loss previously. The

late fetal and neonatal mortality of full term infants behaved in a similar manner. Finally information obtained from the Buffalo City Hospital was presented to show that the incidence of premature birth is in itself of a repetitive character and that mothers who had had a premature birth or miscarriage were much more likely to have a similar occurrence in succeeding pregnancies. This interesting study seems to confirm the practical views already held by many obstetricians that mothers with previous histories of premature births, stillbirths and high neonatal mortality of their infants require exceptionally careful antepartum precautions.

CROSS PURPOSES

An unidentified newspaper clipping, presumably from a Philadelphia newspaper, carries the interesting information that a Philadelphia hospital and an antivivisection organization each received \$5,000 under the will of a woman who also bequeathed \$1,000 to a dog and cat hospital. This is an ironical comment on what was undoubtedly a totally unintended result of these bequests, namely that one of them will be used to defeat the purposes of the other two. The bequest to the hospital and to the dog and cat hospital will be used for the treatment of human beings and animals suffering from disease. This treatment will be preceded by diagnosis based on knowledge obtained from animal experimentation. It will include methods of treatment, both medical and surgical, based on animal experimentation. Even the well chosen diets which will adorn the trays of the human patients and the rations which will restore ailing animals to their owners in prime condition are computed on the basis of information depending in large part on animal experimentation. The bequest to the antivivisection society will be used to cripple, harass and defeat the efforts of scientists to use animals in the investigation of the remaining problems and mysteries in the field of health and disease. Thus unconsciously this testator has made one bequest which will neutralize and set at naught the effects of another.

EXPERIMENTAL POLIOMYELITIS AND SULFAPYRIDINE

It having been previously shown that sulfanilamide is without effect in the prevention of experimental poliomyelitis,¹ Toomey and Takacs,² using sulfapyridine, injected intracerebrally each of eight *Macacus rhesus* monkeys with 0.5 cc. of 1 per cent purified virus suspension of Flexner's M. V. strain. Two days later four of the animals received 0.5 Gm. of purified sulfapyridine twice daily for from seven to ten days, when massive paralysis appeared. All eight animals developed poliomyelitis within seven to ten days after injection of the virus, irrespective of administration of sulfapyridine. The investigators conclude therefore that sulfapyridine, like sulfanilamide, is of no value in preventing the production of experimental poliomyelitis in *Macacus rhesus* monkeys injected intracerebrally with poliomyelitis virus.

ORGANIZATION SECTION

THE NATIONAL HEALTH PROGRAM

DIGEST OF THE PRELIMINARY REPORT FROM THE COMMITTEE ON EDUCATION AND LABOR,
SUBMITTED BY SENATOR MURRAY

In submitting its preliminary report (Senate Report No. 1139, 76th Congress, 1st Session) the subcommittee of the Committee on Education and Labor points out that it is in agreement with the general purpose and objectives of the Wagner bill, S-1620, establishing a National Health Program; it wishes, however, to give this legislation additional study and to consult further with representatives of lay organizations and of the professions concerned.

The subcommittee states that it intends to report out an amended bill at the next session of Congress.

I. NEED FOR A NATIONAL HEALTH PROGRAM

The preliminary report states that this bill is the result of several years of preparatory study and discussion and that it grew out of the movement which led to the Social Security Act of 1935, followed by the National Health Conference, the National Health Survey and various other activities.

The evidence presented shows convincingly, the committee believes, that there are great opportunities to improve health conditions in this country. It is felt that we should be able to make still further improvements on the excellent records in the field of health that prevail today. Special reference is made to the opportunity to save lives threatened by tuberculosis. It is said that the funds available for venereal diseases are sufficient to make only a beginning in this campaign.

The report emphasizes that 11,000 mothers died in childbirth in 1937 and alleges that more than one half to two thirds of such maternal deaths are preventable. It is said also that each year nearly a quarter of a million women do not have the advantage of a physician's care at the time of delivery. Vastly more could be done than is being done to conserve the lives and health of children.

The report indicates the belief that only those in the upper income groups receive anything approaching adequate dental care.

There is a discussion of the extra hazards associated with industry, and much is said of the need of new methods of medical service in rural areas.

Emphasis is placed on the statement that there is wide variation among the states in the availability of hospital facilities. With regard to general hospitals, the number of available beds varies among the states from a maximum of 5.2 to a minimum of 1.3 for every thousand of population. The record for the country as a whole indicates an average of 3.1 beds for every thousand persons and the report asserts that adequate standards for general hospitalization call for an average of 4.5 beds in general hospitals for every thousand persons.

There are also great differences among the states in the availability of beds in mental institutions.

COSTS OF ADEQUATE HEALTH SERVICES

The preliminary report calls attention to the fact that there are various factors which explain why large proportions of the population fail to receive the medical

and health service they need. The committee recognizes the fact that ignorance, reliance on unsuitable methods, great distances from physicians, and so on, play a part, but it says that from the evidence placed before it the major reason is lack of financial ability on the part of large portions of the population to meet the costs of needed services. It has accepted the idea that many who could buy medical care on some budget basis find it difficult to purchase service on the customary basis of paying for the care when the need for the care arises.

Figures are cited from the National Health Survey to show that the average number of physician's calls per case is higher among the well-to-do than among the poor. The committee repeats the statement of a witness for the American Medical Association to the effect that among the one fourth of the states with the highest percentage of population filing income tax returns there was an average of one general hospital bed for 261 persons in the population and that these beds were being used 65.5 per cent of their capacity. In the one fourth of the states at the other end of the economic scale there are 549 persons per general hospital bed with an average occupancy rate of only 52 per cent.

Much emphasis is placed on the report supplied by Dr. R. G. Leland, Director of the Bureau of Medical Economics, who testified on behalf of the American Medical Association and who supplied factual data on medical economics.

The committee said "We cannot emphasize too strongly or say too often that when we speak of inadequate medical care, of insufficient services received by large numbers of people, or of the economic problems in paying for care, we are not criticizing the physicians or hospitals or others who furnish services. They have long been performing humanitarian services deserving the highest praise. It is not the responsibility of doctors or hospitals or related groups that large sectors of the population have limited economic resources."

The committee paid tribute also to the work of the voluntary organizations and stated that "every right-thinking citizen will insist that in the health program for the future there shall be adequate provision for the continued vigorous activity of the voluntary organizations."

DISABILITY INSURANCE

The committee believes that the program of social security which this country has established is incomplete without protection of the individual against the risk of losing his earning power because of disability. The committee feels that, if adequate protection against the risk of disability is to be developed, insurance must be made obligatory as has already been done in the case of protection against unemployment in old age.

THE NEED FOR FEDERAL ACTION

The committee argues that it does not propose a new departure or a new type of activity for the federal government. "It is our opinion," it says, "that the administration and operation of health services should

be left to the local communities and to the states, and that the federal government should not control or dictate to the local communities or states in the management of these functions. . . . The primary opportunity for the federal government is to give financial and technical aid to the states."

It is pointed out that the federal government is now providing aid to the states for a variety of purposes having to do with the general welfare and with health. The committee points out that the public hearings have shown that there is a broad and substantial support now for federal legislation to strengthen, extend and improve the health services of our people. Scarcely a witness raised objection to the objectives of the bill, although representatives of some organizations presented serious criticisms.

II. PRINCIPLES UNDERLYING THE BILL

Here the committee presents an analysis of the bill together with statements by Abel Wolman, Dr. Felix J. Underwood, Dr. A. T. McCormack, Dr. Thomas Par- ran and Miss Katharine Lenroot in support of the form of S. 1620.

III. PRINCIPAL PROVISIONS OF THE BILL

There follows an analysis of the bill as it now stands and a table of comparison of present appropriations for health purposes under the Social Security Act and the appropriations proposed to be authorized by S. 1620.

IV. SOME SPECIAL PROBLEMS RAISED IN THE HEARINGS

It is pointed out that some witnesses objected to the grant-in-aid pattern embodied in the bill. The committee felt that the bill would appear to follow a fundamentally sound principle when it leaves to the states the decision as to the population groups to be served by their plans. The committee has under consideration the question of providing funds for federal support of professional education, administrative training and research. The committee is prepared to make the intention of the bill to provide for health education of the public clear and specific.

There is much discussion of the recommendation that one federal agency should administer medical affairs. It is pointed out that further study is required on the matter of the relationship between the Federal Security Administration and the Children's Bureau of the Department of Labor and between them and other federal agencies. There is also the question of having a single federal advisory council or a national health council instead of several federal advisory agencies.

The committee considered particularly the question of the protection of minority population groups and asserts that the committee believes that there should be just and equitable allocation of funds according to the needs for services.

On the question of the eligibility of practitioners from various schools of healing, the committee states that it is impressed by the fact that the licensing and regulation of practitioners in medicine and allied fields have always been within the jurisdiction of the states and not under the federal government, and the committee feels that the powers should be left in these states as at present and that therefore the bill should not include any specifications on these points except a provision to the effect that nothing in the bill should be construed as infringing on the authority of each state to continue to regulate the practice of the healing arts.

On the question of the construction of hospitals, the committee states that this title is not intended to lead

to any unsound activity. Before any new hospital construction is undertaken, the available beds in qualified, existing, nongovernmental and governmental hospitals should be used provided the type of service meets accepted standards and the charges for the use of such beds are reasonable. The committee says "We have no intention whatever of endorsing any proposal that would encourage the building of hospitals where adequate facilities exist or that would encourage the building of public hospitals where private hospital construction would in the normal course of events meet community needs." It says "Furthermore, our committee intends to prepare amendments to title 12 to assure that federal aid under this title will require unequivocally clear showing of need through impartial state and local surveys, and clear satisfaction of federal requirements that such needs exist, in addition to reasonable demonstration as to future continuing support of the hospitals." The report says that "the committee is agreed that the bill should be amended by addition of positive provisions that qualified hospitals and agencies, both public and private, may be utilized in the state plans."

V. CONCLUSION

"S. 1620 has received wide support from large and representative organizations. Its objectives are noncontroversial. Our government is dedicated to promoting the welfare of the people and the protection and improvement of health and well-being. Making available to all of the people the great life-saving services which modern medicine has to offer is an objective which every right-thinking citizen supports.

"The committee is convinced that federal legislation along the general lines followed by S. 1620, based upon federal-state cooperative programs, is necessary to strengthen the health services of the nation and to make provision for the progressive and effective improvement of health conditions in all parts of the country and among all groups of people. The needs are large and an adequate program to put knowledge and skill more effectively to work will involve considerable expenditures of funds. The program must therefore be worked out with great care. We are confident that such a program can be worked out and that the expenditures will be sound national investments which will bring large returns. The rôle of the federal government should be primarily to give technical and financial aid to the states.

"A critical analysis of the present provisions of S. 1620 shows a number of points at which its specific purposes can be more clearly stated and its provisions improved. The committee has not yet reached any conclusions concerning the precise rate at which federal appropriations should be increased, but the committee is agreed on the general principle that the proportion of federal assistance should be greater to those states in which there is the greatest need for the services contemplated under the bill. The committee is prepared to augment the provisions of the bill—if additional provisions are needed—to assure that the amount of federal assistance would in no instance be in excess of clearly demonstrated need.

"Some misunderstandings seem to have arisen and criticisms have been expressed concerning parts of the bill. Some witnesses have assumed that it would bring about revolutionary or dangerous changes in medical care. We think these fears are unwarranted, but we will welcome further suggestions as to specific amend-

ments which may safeguard the objectives of the bill. Medical science has reached a commendable status in this country. The bill should encourage the further evolutionary development of medical science, teaching and practice.

"The committee has received the assurances of many lay and professional groups that they will be prepared to furnish further information and suggestions. We

expect to consult further with representatives of these groups.

"We have not yet had adequate time to make exhaustive study of all of the problems involved in the legislation proposed by S. 1620. The committee will continue its study of S. 1620 so that a definitive report on the proposed legislation can be submitted soon after the beginning of the next session of the Congress."

RESPONSIBILITY FOR GRADUATE EDUCATION

Abridgment of editorial on Graduate Education, appearing in the New England Journal of Medicine 221:118 (July 20) 1939.

There can be no question that the recent growth and development in the art and science of medicine requires practicing physicians to keep abreast of the times. In a recent discussion of graduate education in medicine, Abell¹ calls attention to the increasing need for graduate teaching, which he properly divides into two categories: the one dealing with the preparation and training of specialists, the other concerned with the continued education of those already in active general practice.

This is an age of specialization, and the trend in this direction may well have gone too far. It seems certain, in any event, that entirely adequate means are already at hand to train, through the medium of postgraduate residencies, men properly equipped with an advanced and detailed knowledge of some particular field in medicine. We need have no fear of the lack of specialists. We may possibly view with some apprehension their increasing number.

The more difficult problem is that of aiding the doctor who earnestly desires to add to his medical knowledge and improve his skill as a general practitioner among his fellow men.

It is often assumed that this burden rests entirely on the shoulders of the medical profession. Abell suggests that intra-mural courses, consisting of bedside lectures, be given by medical schools and connected hospitals and that demonstrations and clinical expositions covering topics which the physician meets

in his daily work be offered under the auspices of the various county societies. The implication appears to be that if such courses are offered they will be taken to full advantage and with much enthusiasm by the practicing physician, be he urban or rural. This in many instances proves to be the case, as is shown by the attendance at the various postgraduate meetings held throughout the country. Yet in other instances the reverse is unquestionably true. Instructor physicians of note and ability have been prepared in advance for an audience of a hundred or more and been met by the local chairman, three undergraduate students with an eye to adventure and four graduates whose interest was slight and whose attention was nil.

The proper and adequate preparation of a graduate course in medicine—whether it be in the form of didactic lectures or bedside clinics—is at best difficult. No instructor, however experienced, can go forth unprepared and serve up an intellectual menu which is both palatable and nourishing. Time and thought and energy and patience must be expended if graduate instruction is to bear fruit. On the other hand, the physicians for whom the instruction is planned must have a sincere desire to learn and a great willingness to cooperate in any projected program.

The medical profession has, in a sense, assumed a moral obligation to supply opportunities for the acquisition of further knowledge to those who seek it. Let it shoulder this obligation squarely and sanely. But the practicing physician who would take advantage of this graduate education in medicine—be he old or be he young—must likewise do his share or the seed falls on barren ground. The obligation to teach is no greater than the necessity of keeping intellectually fit.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—The President has signed the following bills: S. 1899, providing for the detail of a commissioned medical officer of the Public Health Service to serve as assistant to the Surgeon General; H. R. 6555, amending the law relating to the advance of funds in connection with the enforcement of acts relating to narcotic drugs so as to permit such advances in connection with the enforcement of the Marihuana Tax Act of 1937; H. R. 6556, providing for the seizure and forfeiture of vessels, vehicles and aircraft used to transport narcotic drugs, firearms, and counterfeit coins, obligations, securities and paraphernalia; and H. R. 6635, amending the Social Security Act and authorizing an increase in appropriations for maternal and child health services and services for crippled children, under the supervision and control of the Children's Bureau, and in appropriations for public health activities, under the supervision and control of the Public Health Service. The Senate has concurred in the House amendments to S. 1540, proposing to increase the compensation of members of the National Advisory Health Council not in the regular employment of the government.

Bill Introduced.—H. R. 6954, introduced by Representative Randolph, West Virginia, proposes to authorize the Secretary of the Treasury to pay \$100, \$90.98 and \$9 respectively to Dr. J. D. Spencer, the Somerset Community Hospital and Adelaide Deitz, a registered nurse, in full settlement of their claims against the United States for surgical, medical, hospital and nursing services rendered by them to an officer of the

United States Infantry Reserve, who was stricken with appendicitis while on leave of absence from active duty with the Civilian Conservation Corps.

DISTRICT OF COLUMBIA

Changes in Status.—The President has signed the following bills: H. R. 4732 and H. R. 4733, respectively providing for the issuance of a license to practice chiropractic in the District of Columbia to George M. Corriveau and to Laura T. Corriveau; and H. R. 7086, providing for insanity proceedings in the District of Columbia. S. 2745 has passed the House, authorizing the Commissioners of the District to promulgate and enforce all such reasonable rules and regulations as they may deem necessary to prevent and control the spread of communicable diseases in the District of Columbia. S. 2779 has passed the House, proposing to eliminate from the healing arts practice act in the District of Columbia the requirement that examinations be held on the second Monday in January and July of each year and to provide that such examinations may be held at such times as the Commission on Licensure to Practice the Healing Art may by rule or by special order determine.

Bill Introduced.—H. R. 7024, introduced by Representative Martin J. Kennedy, New York, proposes to authorize and direct the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice the healing art in the District of Columbia to Dr. Marcel T. Kahn, Washington, D. C.

MEDICAL ECONOMIC ABSTRACTS

STATE MEDICINE VERSUS HEALTH
INSURANCE IN ENGLAND

A possible indication that dissatisfaction with health insurance in England is reaching the point where it may cause the introduction of a system of state medicine is offered by a debate which recently took place in London. In this debate Mr. Somerville Hastings and Dr. D. Stark Murray proposed the motion "that the institution of a whole-time state medical service would be in the interest of the nation's health." This was opposed by Sir Henry Brackenbury and Dr. Frank Gray.

The debate in full, together with the general discussion that followed, is reported in the *Post-Graduate Medical Journal* (15:112-129 [April] 1939). The trend of the debate and the attitude of the debaters, as shown in the extracts that follow, suggest certain opinions and conditions that illuminate some discussions that are taking place in this country.

Mr. Hastings closed his introductory address with the statement:

To sum up then, there is no rational stopping place between the first beginnings of preventive medicine and a fully developed state medical service. If we want to prevent we must treat as well, and if we want to treat intelligently, we must make provision for correct diagnosis and for the recognition of disease at its earliest beginning.

Dr. Murray laid the foundation of his argument for state medicine with the following statements:

I need only remind you of the recently published report on Tuberculosis in Wales to confirm the opinion that not only is the health of the nation in a serious condition but that it can be improved only by radical changes—not only by attending to the sick but by interfering with the environment of the healthy.

Of course the British Medical Association had already convinced most of us that the present organization of our medical services cannot cope with the problem of the nation's health and that the greater part of our population, working-class and middle-class does not receive an adequate medical service. It has even tried to convince the general public that environmental changes will be needed before disease can be conquered but, refusing to look even its own facts in the face, puts forward a scheme which would perpetuate many of the worst features of the present-day position.

Sir Henry Brackenbury, in opposing the motion, makes the following plea for free choice and personal relations between the doctor and the patient:

If I believed that we could deal with either medicine or people in this simple and mechanical fashion I might be inclined to agree with him, for skilled detection and a facility for prescribed classification may be admirable qualities in an official. The truth, on the contrary, is that the general practitioner is dealing not primarily with diseases but with patients; and that a patient is not merely a biological organism but also, at the same time and all the time, a human personality, and a unit in a social system. His doctor should be to him, therefore, not just a disease discoverer and curer but a health adviser, a sympathetic helper, and an understanding friend. The doctor must, of course, have skill and scientific knowledge in a high degree, but to discharge his functions satisfactorily he requires qualities beyond this. It is on account of this threefold character and threefold need of the patient that the general practitioner or family doctor must be made the basic factor of any national medical service, and not merely be an accessory called in to perform certain limited functions. When a person, whether well or ill, feels that he needs health advice or attention, it is wiser that he should seek it primarily via his own doctor rather than via the town clerk, the hospital secretary, or even the medical officer of health. It is, I agree, the state's business to see that everybody is able to secure such a doctor-patient relationship, and to obtain through the general practitioner all such ancillary, consultant, and institutional services as are in his case necessary. It is not impossible to provide a general practitioner service with even wider functions than those contemplated by Mr. Somerville Hastings on a whole-time salaried basis, but there are reasons which show that such a basis must be less satisfactory than any other, whether that other be financed on an insurance system or in some alternative way. Such basis, whatever may be the details of the structure built upon it, may best be described as "free-contract."

Essential conditions for satisfaction and success in such a doctor-patient relationship as I am postulating are that it shall be spontaneous, free, and continuous or enduring.

His further remarks constitute a rebuke to those in this country who underestimate the value of freedom of choice:

I am aware, too, that there are those who attach very little importance to this freedom of choice. I do not agree with them. I regard it as essential to the establishment of the best relation between patient and

doctor; and it must be noted that it is not the wisdom, or propriety of the original choice—which is of the essence of the matter—but rather the freedom to change one's doctor at any time should sufficient reason arise.

Dr. Frank Gray, in supporting Sir Henry Brackenbury, said, in regard to the preventive work of health insurance:

Take National Health Insurance, which, Mr. Hastings admitted, did not fit very neatly into his classified scheme. National Health Insurance has been in existence for twenty-five years, and the Ministry of Health for twenty years. There are 19,000 doctors in National Health Insurance, with no financial interest in the ill-health of their patients. Yet it is a startling fact that the only efforts which have been made during the whole of that time to provide special instruction in preventive medicine for those doctors have been made by two groups of London doctors and not by the Ministry. Could there be a more damning indictment of a government department than to say that for twenty years it has entirely neglected the preventive possibilities of the vast organization it controls?

He concluded:

The future rests with the individual, and the person best able to keep the individual in good health is the doctor who knows him and whom he trusts—his own family practitioner.

In the general discussion which followed, Mr. John Bunyan, a dental surgeon, said:

Then there is the question of National Health Insurance. The conditions may be bad enough for the medical practitioner, but for the dental practitioner they are worse. He is dictated to by the insurance societies, the biggest racketeers of modern times; also by persons whose qualifications appear to be little more than gray hairs and who are allowed to determine the type of treatment to be given to patients. What is more, this treatment is not based on what is best for the patient, it is based on the requirement that it must be the cheapest possible. I have been told by the Ministry of Health that this is an industrial service and that therefore they want it on the cheapest basis. Surely in a nation like ours what is necessary for the national health should be the best that could be obtained, not the cheapest.

Dr. Dennis O. Clark, who characterized himself as "one of those Cinderellas of medicine—the general practitioner," described the work of such physicians under insurance as follows:

In the first place, our work at present is very largely rush work. We work long hours, and ordinarily we can give a very short time to each patient. We have to do it entirely on our own, for there is very little cooperation between practitioners. If we send a patient into hospital we lose sight of him until he comes out again with a most cursory note. I have in my practice patients such as diabetics and heart cases who refuse to go to hospital and cannot afford a consultant. Then, again, a general practitioner is liable to miss a great many symptoms and signs owing to the rush with which his work has to be done. I have tried to take notes for a year or two now of every case I see, and I find that if I see only fifty patients a day I can take sufficient notes for the consultant in any given case to say "Well, this doctor keeps decent notes." But if the number of patients to be seen in a day goes up to seventy-five one's work in this respect deteriorates. One can only get down the name and address of the patient and a quick diagnosis; while in an epidemic, when one may see 100 patients a day, one cannot do even that.

Dr. H. H. MacWilliam sounded like some of the advocates of sickness insurance in this country when he said:

Very few people would dispute the fact that at present the general public are not receiving the medical treatment they need, and the problem is to direct the work of doctors in channels that would be most productive and give the best results.

Dr. E. M. Dimock thinks that "if one examines the alternative to a state medical service, namely, the B. M. A. plan for dependents, it looks . . . very like patchwork." He said concerning graduate work under sickness insurance:

I am sure that the present postgraduate facilities under the National Health Insurance system are only a tit-bit, and something much more radical is required to increase the efficiency of the general practitioner. As it is, our expensive education is largely wasted.

Mr. Hastings, in closing the debate, said:

In speaking at the beginning I avoided the B. M. A. scheme because I thought of it as merely an extension of the panel system to the wives and dependents of insured. How will that panel be appointed? How are insurance doctors appointed now? By the sale of practices, some of those who purchase the practice having the money themselves, and others who borrow it from moneylenders. The widow of the previous doctor is the only person who has any real free choice of doctor in the district. She sells the panel to the doctor she chooses, and such is the inertia of human nature that 90 per cent of the patients take on the doctor to whom they have been sold. Do you think you can have a decent medical service when the people in it buy their appointments?

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Officers.—Dr. Herbert A. McClure, Butler, health officer of Choctaw County, has been appointed to a similar position in Lamar County, with headquarters in Vernon. He succeeds Dr. Daniel R. Brown, resigned.—Dr. Robert K. Wilson, Dothan, has been appointed health officer of Pickens County, succeeding Dr. Horace C. Hunt, Livingston, who resigned to enter the private practice of medicine.

Regional Meeting.—At a meeting of the Northeastern division of the Medical Association of the State of Alabama in Sylacauga June 22 the speakers included:

Dr. James O. Finney, Gadsden, Complications of Peptic Ulcer.
Dr. Frank C. Wilson, Birmingham, Carcinoma of the Colon.
Dr. Virgil P. W. Sydenstricker, Augusta, Ga., A Typical Deficiency Syndrome.
Dr. Joseph T. Banks, Dadeville, Meningitis: Treatment with Sulfapyridine; Report of Two Cases.
Dr. Chalmers H. Moore, Birmingham, Diagnosis of Brain Tumors.
Dr. Sumner D. Davis II, Talladega, Placenta Accreta.

ARKANSAS

Society News.—At a meeting of the Jefferson County Medical Society in Pine Bluff recently Drs. Herbert Fay H. Jones, Little Rock, spoke on "Etiology and Significance of Hematuria"; John W. Smith, Little Rock, "Removal of Foreign Bodies from Stomach and Respiratory Tract," and Frederick W. Hames, Pine Bluff, "Skin Cancer, Prophylaxis and Treatment."—The Benton County Medical Society was addressed at Siloam Springs recently by Drs. Charles T. Chamberlain on "Deficiency Diseases"; Ralph E. Weddington, "Summer Diarrheas," and William O. Arnold, "Treatment of Bronchiectasis." All are of Fort Smith.—Dr. Herman W. Hundling, Little Rock, discussed "Diverticulosis and Diverticulitis of the Bowel" before the Pulaski County Medical Society recently.—At a recent meeting of the Union County Medical Society Drs. Rufus B. Robins, Camden, presented "A Review of the Treatment of Acute Head Injuries" and David Harvey Shipp, Little Rock, "Surgical Treatment of Pulmonary Tuberculosis."

New Head of Crippled Children's Division.—Dr. Ellery C. Gay, Little Rock, has been appointed medical supervisor of the crippled children's division of the state department of public welfare, serving on a part time basis. He succeeds Dr. Lee Vallette Parmley, resigned. Dr. Gay was formerly a member of the staff of the division. New plans under consideration feature expanded services to crippled children throughout the state, provide for the use of six hospitals in treating crippled children and a convalescent home for after-care. The institutions are the Arkansas Children's, Baptist State and the city hospitals and St. Vincent's Infirmary, Little Rock; Davis Hospital, Pine Bluff, and Leo N. Levi Memorial Hospital, Hot Springs. The convalescent home is in Little Rock. More than 800 crippled children are receiving care, treatment or supervision by the division, it was stated; more than 1,500 have been registered and examined, as compared with the 330 patients who were being cared for in February 1938. A survey is also being planned to determine the number of crippled children in the state.

CALIFORNIA

State Medical Library Taken Over by University.—The California State Medical Library was discontinued June 30. Its work is being carried forward by the University of California Medical Center Library, San Francisco, according to the *Bulletin* of the Los Angeles County Medical Association. The subscription lists from the Los Angeles branch are being transferred to the medical center library and the periodicals are being circulated from San Francisco to the state medical library subscribers all over the state. The university library has received an additional appropriation from the regents for this work. The publications purchased under the state medical library funds will remain on deposit in the university. At Los Angeles they will remain at the medical department in the custody of Bennett M. Allen, Ph.D. It is planned to maintain the files of these periodicals at Los Angeles from duplicates acquired in the medical center library.

FLORIDA

Clinical Conference.—The fifth annual clinical conference of the Florida section of the Southeastern Surgical Congress, in cooperation with the Marion County Medical Society and the Munroe Memorial Hospital, Ocala, will be held in Ocala August 24. The program will consist of the presentation of cases and case reports followed by discussions from the floor. There will be no set papers. Included among the speakers will be:

Dr. Edgar F. Fincher, Atlanta, Ga., Head Injuries.
Dr. William A. Selman, Atlanta, Tumors of the Breast.
Dr. Turner Z. Cason, Jacksonville, Errors Which May Lead to Unnecessary Surgery.
Dr. Robert L. Sanders, Memphis, Tenn., president of the congress, Diagnosis and Management of Surgical Lesions of the Colon.
Dr. Benjamin T. Beasley, Atlanta, secretary of the congress, Aims of the Southeastern Surgical Congress.
Dr. John S. Turberville, Century, president-elect, Florida Medical Association, Complications in Gallbladder Surgery.
Dr. Julian K. Quattlebaum, Savannah, Ga., Surgical Treatment of Gastric and Duodenal Ulcers.
Dr. Grady O. Segrest, Mobile, Ala., Cardiac Irregularities as Related to Surgery.

GEORGIA

Society News.—Dr. Robert B. Greenblatt, Augusta, discussed "Study and Treatment of Amenorrhea and Menometrorrhagia" recently before the Macon Medical Society of Bibb County. Dr. John D. Bradley, Macon, read a paper before the society July 4 on "Bronchial Asthma."—At a recent meeting of the Georgia Medical Society, Savannah, Drs. Charles C. Hedges, Suffolk, Va., read a paper entitled "The Control of Advertising and Its Integration with the Health Program" and Dr. Edward J. Whelan, Savannah, presented a case report on "Intracapsular Fracture of the Neck of the Femur."

County Society Joins Antisiphilis Campaign.—At a meeting of the Fulton County Medical Society, resolutions were adopted requesting the members to cooperate in the control and proper treatment of syphilis. A minimum fee of \$1 a treatment was established, higher fees to be charged in accordance with the patient's ability to pay. Participation in the program is voluntary on the part of the members of the society. The state department of health has made available free antisyphilitic drugs for the treatment of all patients, regardless of their financial status. Free laboratory diagnostic services are also available through the central laboratory at the state capitol in Atlanta and the two branch laboratories in Waycross and Albany.

District Meeting.—At the summer meeting of the First District Medical Society in Savannah July 19 the speakers included Drs. Exum B. Walker, Atlanta, on "Sciatica: Its Cause and Treatment"; Lehman W. Williams, Savannah, "Operation for Anal Incontinence"; Leonard J. Hahne and Julian K. Quattlebaum, Savannah, "Operation for Fibroid Tumor"; James G. Lyerly, Jacksonville, Fla., "Some Neurosurgical Considerations of Epilepsy"; Robert Randolph Jones Jr. and Donald S. Martin, both of Durham, N. C., "Value of Sterilization of the Operating Room Air by Ultraviolet Light," and William H. Myers, Savannah, president, state medical association, "Relation of the County Medical Society to the Community."

IDAHO

State Medical Meeting at Boise.—The forty-seventh annual meeting of the Idaho State Medical Association will be held at the Owyhee Hotel, Boise, August 23-26, under the presidency of Dr. Frank C. Gibson, Potlatch. The guest speakers, all members of the faculty of Washington University School of Medicine, St. Louis, will give several addresses each, as follows:

Dr. Franklin E. Walton, Surgical Significance of Jaundice; Modern Trends in Medical Education.
Dr. David P. Barr, Influence of the Pituitary Gland on Bodily Function and Disease; Clinical Management of Lobar Pneumonia; Vitamins and Their Clinical Importance; Diagnosis and Treatment of Parathyroid Disease.
Dr. Alexis F. Hartmann, Infant Feeding; Present Status of Chemotherapy with Sulfanilamide and Derivatives; Practical Aspects of Parenteral Fluid Administration; Present Status of Prophylactic and Immunizing Procedures Against the Acute Infectious Diseases.
Dr. Otto H. Schwarz, Management of Breech Presentation; Cesarean Section; Puerperal Infection; Toxemia of Pregnancy.
Dr. Nathan A. Womack, Carcinoma of the Lung; Surgical Treatment of Fractures of the Femur; Tumor of the Breast; Pathology of Cholecystography with Relation to Symptoms.
Dr. Sherwood Moore, Hyperostoses of the Skull and the Associated Symptom-Complex; Present Day Methods of Irradiation of Malignant Surface Lesions; An Appraisal of Cholecystography Over a Fifteen Year Period; Body Section Radiography with the Laminagraph Demonstration of a Simple Modification.

The annual golf tournament will be played Friday afternoon August 25 and the annual banquet will be Thursday evening. The Woman's Auxiliary will hold its meeting during the association's meeting.

ILLINOIS

Society News.—At a meeting of the Madison County Medical Society in Alton August 4 the speakers were Drs. Isaac A. Abt, Chicago, on "Infant Feeding First Two Years"; John F. Carey, Joliet, "Treatment of the Sick Infant," and Franklin J. Corper, Chicago, "Respiratory Tract Infections in Children."

Health Exhibits at the State Fair.—State fair visitors were invited to have free blood tests made by the state department of health during the week of the fair, August 12-19. Code numbers were used instead of names in order to keep the results confidential. A special laboratory was established on the grounds and the visitors were invited to see the process and hear it explained by a lecturer. The department also conducted a "better babies conference" and presented numerous exhibits and demonstrations. Among the latter were an exhibit on pneumonia, models showing care of patients with contagious disease, a modern swimming pool and a giant tooth showing principles of dental hygiene.

Chicago

A Year Without a Maternal Death.—There were 2,748 deliveries without a maternal death in the Chicago Lying-In Hospital of the University of Chicago during the fiscal year ended June 30. In 571 deliveries of the hospital's home service there was but one death.

Personal.—Arnold F. Emch, Ph.D., has resigned as executive director of the Chicago Hospital Council to become assistant secretary of the American Hospital Association. — Sr. Surg. William H. Slaughter has been appointed medical officer in charge of the U. S. Marine Hospital, succeeding Dr. Mark J. White, who retired May 1. Dr. Slaughter comes from a similar post in New Orleans, where he was succeeded by Dr. Lionel E. Hooper, Honolulu. — Dr. Clement C. Clay, medical assistant to the director, University of Chicago Clinics, has resigned to become administrator of St. Barnabas Hospital, Minneapolis, succeeding Samuel W. Rice, resigned.

INDIANA

Regional Conferences Continued.—A postgraduate conference on obstetrics was held at St. Mary's Hospital, Evansville, August 8, for physicians in the First District Medical Society of the state medical association under the auspices of the Vanderburgh County Medical Society. This session was one of a series of conferences conducted on the second Tuesday of each month. The speakers at the August program included Drs. Carl P. Huber, resident adviser and research director in obstetrics and gynecology, Indiana University School of Medicine, Indianapolis, on "Toxemias of Pregnancy," and Nicholson J. Eastman, professor and director of the department of obstetrics, Johns Hopkins University School of Medicine, Baltimore, "Hemorrhage During Pregnancy and Labor." Subsequent monthly programs will be devoted to pediatrics, tuberculosis, traumatic surgery, orthopedics and pneumonia. The Grant County Medical Society held the first of these regional conferences June 13-15 in Marion.

MAINE

Members of Medical Board.—With recent appointments by Gov. Lewis O. Barrows, the Maine Board of Registration in Medicine is now made up of the following: Drs. John G. Towne, Waterville, chairman; Adam P. Leighton, Portland, secretary; George R. Hagerthy, Bar Harbor; Oscar R. Emerson, Newport; Franklin A. Ferguson, Portland, and Currier C. Weymouth, Farmington. Dr. Ferguson fills the vacancy left by the death of Dr. Ralph D. Simons, Gardiner, and Dr. Weymouth was appointed to succeed Dr. Robert J. Wiseman, Lewiston. Dr. Leighton is serving his twenty-fifth year as a member and secretary of the board.

MARYLAND

Red Cross Blood Donor Service.—The volunteer blood donor service organized by the Baltimore chapter of the American Red Cross finished its first year July 1. The service enlisted 517 persons as volunteer donors. The chapter received 481 applications, of which 325 were honored as being legitimate claims and 305 donors were sent. Forty-nine of the donors were not used. The recipients were 198 patients in nineteen Baltimore hospitals; no requests were received outside of hospitals. The number of donations made was more than twice that which was anticipated. The service cost the chapter for operating expenses \$9,532.08. This service has been guided by a special committee and aided by other committees of the chap-

ter as well as by practically all the civic organizations in the city. Dr. Charles C. W. Judd is director of the blood transfusion bureau, which was established under the direction of Dr. John M. T. Finney Sr.

MASSACHUSETTS

Course in Public Health Engineering.—A new graduate course in public health engineering has been established at the Massachusetts Institute of Technology to consider such subjects as water supplies, water purification, sewerage, industrial waste disposal, stream pollution and purification and the sanitation of shellfish grounds. In addition, consideration will be given to the most advanced practice in the collection and disposal of refuse, sanitation of swimming pools, rural communities and camps, as well as the sanitation of food supplies, stores and restaurants. Students will also receive instruction in the relationship of insects and rodents to disease, the atmosphere in relation to health and comfort, housing and health, school sanitation and industrial hygiene. There will also be training in the organization and activities of health departments, the collection, analysis and interpretation of vital statistics, epidemiologic methods, the value and conduct of public health surveys and the use of standard health appraisal forms. The course will begin with the opening of the school year September 25 and will lead to the degree of master of science in one year. Additional information may be obtained from Samuel C. Prescott, Sc.D., dean of science and head of the department of biology and public health at the institute, Cambridge, Mass.

MICHIGAN

Commission to Direct Fight on Infantile Paralysis.—Formation of the Michigan Poliomyelitis Commission to arrange consultation service for early diagnosis and prompt orthopedic care of patients in the current outbreak was announced August 10. Members of the commission are:

Dr. Edgar E. Martmer, Detroit, representing the American Academy of Pediatrics, chairman of the commission.
Dr. Henry Allen Moyer, state health commissioner, Lansing.
Dr. James D. Bruce, vice president in charge of postgraduate medical education, University of Michigan Medical School, Ann Arbor.
Dr. Stuart Fritchard, director of the W. K. Kellogg Foundation, Battle Creek.
Dr. Bernard W. Carey, Detroit, medical director, Children's Fund of Michigan.
Dr. Ledru O. Geib, Detroit, chairman of the preventive medicine committee, Michigan State Medical Society.
Dr. Harold Fenech, Detroit, member of the state crippled children's commission.
Dr. Albert S. McCown, deputy state commissioner of health, Lansing.
Dr. Carl E. Badgley, Ann Arbor, representing the Michigan Orthopedic Society.
Dr. Wayne S. Ramsey, Lansing, secretary, Michigan Crippled Children's Commission.
Mr. Edward H. Williams, Detroit, member, Wayne County board of auditors.

The commission has received \$10,000 from the Michigan State Medical Society, the Michigan Society for Crippled Children, the Michigan Crippled Children's Commission, the Children's Fund, the Kellogg Foundation and the Wayne County board of auditors. The state has been organized into sixteen districts, in which consultation service will be maintained. County, city and district health officers will act as clearing agents in obtaining consultants for physicians. In twenty-three counties that do not have full time health service, the presidents of the county medical societies will arrange for the service. Headquarters of the service will be at 614 State Office Building, Lansing. The most recent report of cases for the state, issued August 10, showed that there were ninety-three cases from January 1 to July 31 and from August 1 to 10 there were eighty-six. Of the August cases, sixty-two were in Detroit and the others in counties outside the city as follows: Muskegon, one; Bay, two; Saginaw, three; Tuscola, one; Genesee, two; Oakland, eight; Wayne, six, and St. Clair, one. Twelve have been reported from Windsor, Ont., across the border from Detroit. Dr. Don W. Gudakunst, state health officer up to July 31, has joined the U. S. Public Health Service and has been assigned to represent the service in handling the Michigan epidemic.

MINNESOTA

Personal.—Dr. Donald C. Balfour, Rochester, was made an honorary fellow of the Royal College of Surgeons of England at a meeting July 13. — Dr. Herman E. Hilleboe, St. Paul, has been appointed chief of the medical unit in the social welfare division of the new state department of social security, newspapers recently reported. Dr. Hilleboe, who was director of the division of tuberculosis and services for crippled children under the defunct state board of control, will continue those functions in the new position and will also head the county tuberculosis sanatorium program and the work formerly

MEDICAL NEWS

691

handled by the division of the deaf in the industrial commission. In addition, he will serve as consulting medical official in matters of aid to dependent children, old age assistance and other services in which medical advice is required by the social security set-up. Dr. Hilleboe was one of four United States delegates to the fourth World Conference of Workers for the crippled held in London July 16-22, it is reported.

MISSOURI

New Professor of Pathology.—Dr. Robert A. Moore, associate professor of pathology, Cornell University Medical College, New York, has been appointed Edward Mallinckrodt professor of pathology at Washington University School of Medicine, St. Louis, it is reported. Dr. Moore graduated at the Ohio State University College of Medicine, Columbus, in 1928.

Physician Honored.—A barbecue was held by the Boone County Medical Society recently at the Pinnacles north of Columbia to mark the retirement of Dr. Frank G. Nifong, after fifty years in the practice of medicine. About guests from all parts of the state attended, according to a medical journal. He was presented with a medalion. Nifong graduated at the Missouri School of Medicine at the University of the Health program at Stephens College, Columbia. In 1927-1928 Dr. Nifong was president of the Missouri State Medical Association and in 1933 of the Boone County Medical Society.

NEBRASKA

Personal.—Dr. Floyd H. Kinyoun has resigned as health officer of Omaha to enter private practice in Los Angeles, it is reported. Dr. Victor E. Levine, professor of biological chemistry and nutrition and head of the department of biological University School of Medicine, Omaha, is on his fifth trip to the Arctic, continuing his medical and biologic research on the Eskimo, under the auspices of the U. S. Public Health Service. His base is Kotzebue, north of the Arctic Circle.—Dr. Herbert B. Kennedy, Omaha, has been appointed medical director of the Woodmen of the World Life Insurance Company.

NEW YORK

Society News.—The semiannual meeting of the Franklin County Medical Society was held at Saranac Lake recently with the following speakers: Drs. William Warriner Woodruff on "Fractures of the Neck of the Femur"; LeRoy H. Wardner, "Sulfapyridine in Pneumonia"; Edwin M. Jameson, "Some Common and Uncommon Urological Conditions," and John R. Murphy, "Pyloric Stenosis in the Newborn." Drs. A. J. Vorwald and Daniel M. Brumfiel conducted a pathologic conference.—Dr. James F. Rooney, Albany, and Carl S. Salmon, attorney-at-law, Amsterdam, addressed the Medical Society of Montgomery County June 20 at Canajoharie on "Modern Concept of Coronary Disease" and "Medical Jurisprudence" respectively.

New York City

Faculty Changes at New York University.—Dr. John C. A. Gerster has been appointed clinical professor of surgery at New York University College of Medicine. The following promotions have also been announced:
Drs. Currier McEwen, Elaine P. Ralli, William Goldring and Norman H. Jolliffe, to be associate professors of medicine.
Drs. Herbert Chasis and Evan W. Thomas, assistant professors of medicine.
Drs. Morris Block and Marshall S. Brown Jr., assistant professors of clinical medicine.
Drs. William Howard Barber and George A. Koenig, associate professors of surgery.
Dr. Louis C. Lange, clinical professor of surgery.
Dr. Frank C. Combes, associate professor of dermatology and syphilology.
Dr. Evan W. Thomas, assistant professor of dermatology and syphilology.
Dr. Arno E. Town, assistant professor of ophthalmology.
Dr. Amedeo S. Marrazzi, assistant professor of pharmacology.
Dr. Abram Blau, assistant clinical professor of psychiatry.
Unlicensed Practitioners Prosecuted.—Dalbino F. Fernandez, Long Island City, was recently convicted of practicing medicine without a license, the state board of medical examiners reports. He was sentenced to pay a fine of \$250 or spend thirty days in prison; in addition he received a sentence to three months in the workhouse, with execution suspended pending good behavior. Giuseppe Santangelo, 339 East One Hundred and Eighth Street, was convicted on the same charge

June 9. His sentence was a fine of \$200 or sixty days in the city prison and, in addition, six months in the workhouse with execution of this sentence suspended. Benjamin B. Brown, a pharmacist, was convicted July 28 of practicing medicine without a license; he was sentenced to spend sixty days in the workhouse, with the sentence suspended.

Gastrointestinal Disease Among Nurses.—Two outbreaks of gastrointestinal disturbance in hospitals have recently been reported. At Mount Sinai ninety-three nurses were ill of bacillary dysentery in an outbreak that began June 22. In a statement published in the New York Medical Week, July 15, Health Commissioner John L. Rice reported that in addition to the ninety-three nurses who had been ill about sixty others had been found harboring the dysentery bacillus. A dysentery bacillus carrier was found among the food handlers in the nurses' kitchen. No hospital patients were found to be infected. About fifty nurses and interns were briefly ill at the Presbyterian Hospital about June 25, Dr. Rice reported. In the routine laboratory investigation *Bacillus aertrycke* was identified, but no evidence of infection among food handlers was found.

NORTH DAKOTA

Personal.—Dr. William H. Bodestab, Bismarck, has recently been appointed medical adviser for the North Dakota Workmen's Compensation Bureau, according to the *Journal-Lancet*.—Dr. John G. Lamont, Minneapolis, has been appointed superintendent of the Grafton State School, Grafton, to succeed Dr. Frank W. Deason, resigned.

OHIO

Annual District Meeting.—The Eighth District of the Ohio State Medical Association held its annual spring meeting in June for the twelfth year at Rocky Glen Sanatorium, McConnellsville. The occasion was made a celebration of the twentieth anniversary of Dr. Louis Mark's association with the sanatorium as medical director. Several members of the staff have also been with the institution twenty years. Speakers on the scientific program were Drs. Theodore T. Zuck, Cleveland, on "Relation of the Fertile Time to the Menstrual Cycle"; Verne A. Dodd, Columbus, "Disease of the Stomach from the Surgical Viewpoint" and Judson D. Wilson, Columbus, "Low Back Pain."

OREGON

Personal.—Dr. Horace G. Miller, recently on the staff of the Oregon State Hospital, Salem, has been appointed superintendent of the Oregon Fairview Home for feeble-minded.—Dr. Eugene W. Rockey, Portland, has been appointed chief of staff of the Industrial Accident Commission, succeeding Dr. Louis P. Gambee. Dr. Rockey held this position once before.—Dr. Richard H. Wilcox, Pierre, S. D., has been appointed health officer of Umatilla County to succeed Dr. Alfred H. MacLaren, who will enter private practice in California.

SOUTH CAROLINA

Annual Piedmont Assembly.—The fifth annual Piedmont Postgraduate Clinical Assembly will be held in Anderson September 19-21, with afternoon and evening sessions. The first afternoon the speakers will be:
Dr. Virgil P. W. Sydenstricker, Augusta, Ga., Incomplete Deficiency Syndromes.
Dr. Robert Wilson Jr., Charleston, Diabetes and the Use of Protamine Insulin.
Dr. Angus Murdoch McBryde, Durham, N. C., The Premature Infant.
In a symposium on pathology the speakers announced are:
Dr. Thomas R. W. Wilson, Greenville, Pathology—Looking Backward Thirty Years.
Dr. Edgar R. Pund, Augusta, Ga., Ovarian Tumors.
Dr. Ernest B. Saye, Spartanburg, Tetanus.
Dr. James M. Northington, Charlotte, N. C., Avitaminosis.
Dr. Roy R. Kracke, Emory University, Ga., Effects of Analgesic Drugs on the Blood.

There will also be a symposium on cancer as follows:
Dr. Kenneth M. Lynch, Charleston, Some Things We Know About Cancer.
Dr. Hayes E. Martin, New York, Diagnosis and Curability of Intra-Oral Cancer.
Dr. John Shelton Horsley, Richmond, Va., Cancer of the Stomach and Small Bowel.
Dr. Le Grand Guerry, Columbia, Cancer of the Breast.
Dr. William Lloyd Aycock, Boston, will speak at an evening meeting on "Modern Conception of Contagious Diseases, Including Poliomyelitis" and Drs. Horsley and Oren Moore, Charlotte, N. C., on "Cancer of the Colon and Rectum" and "Indications for Performing Therapeutic Abortions and Sterilizing Operations" respectively.

TENNESSEE

Society News.—The Chattanooga and Hamilton County Medical Society held a special meeting July 12 at which the speakers were Drs. Robert S. Dinsmore, Cleveland, on "Tumors of the Neck"; Bernard H. Nichols, Cleveland, "Hydronephrosis," and Bela Lorincz, Ujpest, Hungary, "Functional Investigation of Contracted Pelvis."—Drs. Carter Hal Henard, Mosheim, and James T. Campbell, Greeneville, addressed the Greene County Medical Society, Greeneville, July 4, on hysteria and ectopic pregnancy, respectively.—Dr. Ethelbert C. Williams, Watertown, addressed the Wilson County Medical Society, Lebanon, in June on early diagnosis and radium treatment of cancer.—Dr. William C. Chaney, Memphis, among others, addressed the Gibson County Medical Society, Humboldt, recently on new methods of treating migraine.

TEXAS

Personal.—Dr. James Shirley Sweeney, Dallas, received the honorary degree of doctor of laws from Texas Christian University at the recent commencement.—Dr. Melvin L. Hutcheson, Denton, has been appointed health officer of Denton County.—Dr. James R. Barcus, Gladewater, has been appointed health officer of the town.—Dr. John G. Welch, Port Neches, has been made health officer of Beaumont.—Dr. Charles F. Hull, Carthage, has been appointed health officer of Panola County.

Dr. Red Honored.—The Harris County Medical Society and its Woman's Auxiliary gave a dinner at the Houston Club recently in honor of Dr. Samuel C. Red, Houston, a founder of the society, at the conclusion of fifty-two years of medical practice. Dr. Reuben M. Hargrove, Houston, was master of ceremonies and various speakers paid tribute to Dr. Red, who made the principal address of the evening. Dr. Red has twice served as president of the county society and has also been president of the State Medical Association of Texas and a delegate to the American Medical Association. He was born in Texas in 1861 and graduated from Jefferson Medical College, Philadelphia, in 1887. A feature of the evening was the presentation to the society of a portrait of Dr. Ashbel Smith, pioneer Texas physician who was a friend of Sam Houston and prominent in Texas history. The portrait was painted by Mrs. Anna Allen Wright, an adopted daughter of Dr. Red, who has written a biography of Dr. Smith.

VIRGINIA

Half a Century at State Hospital.—Dr. Joseph S. DeJarnette, superintendent of the Western State Hospital, Staunton, was honored at a luncheon and special meeting at the hospital July 21 for his completion of fifty years on the hospital staff. Governor Price, Dr. Hugh C. Henry, state director of hospitals, Richmond, and other public officials paid tribute to Dr. DeJarnette. About 300 persons attended. Dr. DeJarnette was graduated from the Medical College of Virginia in 1888 and began his career at the Western State Hospital the same year as third assistant physician. He became superintendent in 1906.

WASHINGTON

Golden Jubilee of State Association.—The Washington State Medical Association will celebrate its golden jubilee at its annual meeting in Spokane August 28-30 with headquarters at the Davenport Hotel and under the presidency of Dr. Harry E. Rhodehamel, Spokane. A special golden jubilee program will be held Tuesday afternoon August 29, at which Gov. Clarence D. Martin and other guests have been invited to speak. Dr. Olin West, Chicago, Secretary and General Manager of the American Medical Association, will be the principal speaker at an economic session. His subject will be "The American Medical Association: Its Organization and Purposes." Guest speakers for the scientific program are from the faculty of Washington University School of Medicine, St. Louis, and will give several papers each, as follows:

Dr. David P. Barr, Vitamin Therapy; Treatment of Lobar Pneumonia.
Dr. Alexis F. Hartmann, Present Status of Chemotherapy with Sulfanilamide and Sulfapyridine; Some Aspects of Parenteral Fluid Therapy; Some Aspects of Infant Feeding; Hypoglycemia in Infants and Children.
Dr. Sherwood Moore, Appraisal of Cholecystography Over Fifteen Year Period; Irradiation Treatment of Surface Malignancies; Hyperostoses of Skull and Associated Symptom-Complex.
Dr. Nathan A. Womack, Indications for and Prognosis in Cholecystectomy for Cholecystitis; Newer Aspects of the Nature of Cancer.
Dr. Otto H. Schwarz, Puerperal Infection; Breech Presentations; Late Toxemias of Pregnancy; Cesarean Section.

The Golden Jubilee Banquet will be held Wednesday evening August 28. The Woman's Auxiliary will hold its eighth

annual meeting during the three days of the association meeting. The program will include greetings from the officers, an address by Dr. West and one by Dr. Hartmann on "Prophylaxis Against Contagious and Infectious Diseases." Mrs. Richard E. Ahlquist, Spokane, is president of the auxiliary.

WEST VIRGINIA

State Medical Meeting and Election.—Dr. Frank V. Langhitt, Clarksburg, was elected president of the West Virginia State Medical Association at the annual meeting in White Sulphur Springs July 10-12. Drs. Thomas F. E. Bess, Keyser, and Alston G. Lanham, Ronceverte, were elected vice presidents. Guest speakers who addressed a general assembly were:

Dr. William Thornwall Davis, Washington, D. C., The Problem of Headache.
Dr. Edward Clay Mitchell, Memphis, Tenn., Sinus Disease in Children.
Dr. George E. Bennett, Baltimore, Bursitis and Other Painful Conditions of the Shoulder.
Dr. Thaddeus L. Montgomery, Philadelphia, Obstetric Problems with the Conflicting Interest of the Mother and Child.
Dr. William B. Porter, Richmond, Pathologic Physiology of Edema, with Special Reference to Its Treatment.
Dr. Donald E. Brace, Woodside, N. Y., The Significance of Oxygen to the Surgical Patient.
Dr. Charles W. Mayo, Rochester, Minn., Concentrated Oxygen and Its Therapeutic Application in Surgery.
Dr. William J. Engel, Cleveland, The Causes and Prevention of Pre-operative Death in Prostatic Hypertrophy.
Dr. Jesse G. M. Bullowa, New York, Pneumonia Therapy.

At this session Dr. Robert J. Wilkinson, Huntington, delivered the annual oration on surgery on "The Surgeon's Responsibility in This Changing World" and Dr. Richard O. Rogers, Bluefield, the oration on medicine, "The Character and Significance of Heart Pain." Several of the guests addressed section meetings and meetings of special societies. The West Virginia Society of Industrial Physicians and Surgeons, the West Virginia Obstetrical and Gynecological Society and the West Virginia Heart Association held their annual meetings during the period of the association meeting.

PUERTO RICO

Ophthalmic Institute Opened.—The Ophthalmic Institute of Puerto Rico, established in 1937 by Drs. Luis J. Fernandez-Garcia and Ricardo F. Fernandez in San Juan, recently moved into a new building in Puerta de Tierra, near San Juan. The new institute, built at a cost of about \$70,000, has four floors. On the first are the offices; on the second private rooms and an operating suite; on the third wards, and on the fourth living quarters for the resident staff. In the basement is a dispensary. Dr. Luis J. Fernandez-Garcia, a graduate of the University of Maryland School of Medicine in 1917, is director and chief surgeon and Dr. Ricardo F. Fernandez, a graduate of George Washington University School of Medicine, Washington, D. C., in 1931, is assistant surgeon.

GENERAL

Theobald Smith Award to Dr. Sabin.—Dr. Albert B. Sabin of the Rockefeller Institute for Medical Research was chosen to receive the Theobald Smith Award of \$1,000 from the American Association for the Advancement of Science at the summer meeting in Milwaukee. The honor came to Dr. Sabin in recognition of his rapid method of typing in pneumonia and for a quick bedside test of a patient's probable resistance to the disease.

Society News.—New officers of the American Physicians' Art Association who took office July 1 include Drs. Henry N. Moeller, New York, president; Edward E. Woldman, Cleveland; Herbert L. Treusch, Atlanta, Ga., and Alfred Braun, New York, vice presidents. Dr. Raleigh W. Burlingame, San Francisco, is treasurer; Drs. Max Thorek, Chicago, and Francis H. Redewill, San Francisco, are recording and corresponding secretaries, respectively. The next exhibition of the association will be during the Annual Session of the American Medical Association in New York June 10-14, 1940.

Library Association Election.—Col. Harold W. Jones, librarian of the Army Medical Library, was elected president of the Medical Library Association at the annual meeting in Newark, N. J., in June. Dr. John M. Armstrong, St. Paul, was elected vice president and Miss Anna C. Holt, Boston, is chair-secretary. Miss Mary Louise Marshall, New Orleans, is Miss of the executive committee and new members are Miss Isabelle T. Anderson, St. Paul, and Mrs. Marjorie Hutchins Moore, Chicago, librarian of the American Medical Association. The 1940 meeting will be in Portland, Ore.

Steamship Passenger Develops Smallpox.—A passenger who boarded the S. S. *Saturnia* of the Italian Line in Lisbon, Portugal, and landed in New York August 1 developed smallpox August 3, the U. S. Public Health Service has reported. Local health authorities in the home towns of all the 450 passengers have been notified to examine the passengers and keep them under surveillance for fourteen days. It is believed that the disease was acquired in Lisbon, as the consular bill of health showed thirteen cases of smallpox in the city. The *Saturnia* had left New York en route to Italy before the case of smallpox was discovered but officials were notified by radio, and the crew of about 400 was vaccinated. All persons embarking at Lisbon will be vaccinated until further notice.

Longevity of Industrial Policyholders.—A new high point of 61.94 years for the expectation of life at birth for industrial policyholders of the Metropolitan Life Insurance Company was reached in 1938 as a result of the unusually favorable mortality conditions prevailing during that year, according to the *Statistical Bulletin*. By achieving this mark the group of insured wage earners and their dependents have established a gain of 15.31 years in their expectation of life at birth since 1911-1912, the earliest period for which a corresponding life table was prepared. Thus, in twenty-eight years, industrial policyholders have increased their average length of life (expectation of life at birth) by practically one third over the initial point, namely, 46.63 in 1911-1912. In the comparison with 1938 over 1937 it was found that, on the whole, the gain was somewhat greater among men than among women. In 1938 at age 5 white males had an expectation of life of 59.62 years, an increase of 1.18 years since 1937, while white females had an expectation of life of 63.77 years at age 5, a gain of 1.04 years since 1937. Corresponding gains for Negroes were 1.88 years since 1937, 7.96 years at age 5, a gain of 1.04 years since 1937. Among the white males at age 5 the expectation of life for the females is 5.59 years below that for white persons. Among Negroes the difference is even greater, namely, 7.96 years. However, these differences seem to vanish with advancing age and at the high ages seem to vanish completely. On the whole, it was stated, longevity among industrial policyholders of the Metropolitan Life Insurance Company is gaining more rapidly than it is in the general population of the United States.

Rocky Mountain Medical Conference.—The second Rocky Mountain Medical Conference will be held at the Hotel Utah, Salt Lake City, September 5-7. The speakers will include:

- Dr. Conrad J. Baumgartner, Los Angeles, Differential Diagnosis of Neck Pathology.
- Dr. Robert H. Herbst, Chicago, Fibrosis of the Neck of the Bladder.
- Dr. Waltman Walters, Rochester, Minn., Benign and Malignant Tumors of the Stomach.
- Dr. Elliott P. Joslin, Boston, Complications of Diabetes.
- Dr. Leo Burger, Los Angeles, Pathology and Pathogenesis of Buerger's Disease.
- Dr. John S. Lundy, Rochester, Minn., Local and Combined Anesthesia.
- Dr. Isaac A. Abt, Chicago, Hormones in Relation to Growth and Development.
- Dr. Herbert E. Schmitz, Chicago, Treatment of Cancer of the Uterus.
- Dr. Ko K. Chen, Indianapolis, Cardiac Drugs of Plant and Animal Origin.
- Dr. Eldridge L. Eliason, Philadelphia, Surgical Jaundice.
- Dr. Elexious T. Bell, Minneapolis, Primary Hypertension and Hypertensive Nephritis.
- Dr. Rudolf Schindler, Chicago, Clinical Gastritis.
- Dr. Ralph K. Ghormley, Rochester, Ununited Fractures of Both Bones of Forearm.
- Arthur H. Smith, Ph.D., Detroit, Metabolic Significance of the Vitamins.
- Dr. Alexander Marble, Boston, Diabetic Coma and Its Treatment.
- Dr. Brien T. King, Seattle, A New Function-Restoring Operation for Bilateral Abductor Cord Paralysis.
- Dr. Arthur E. Smith, Los Angeles, Skin Grafting with a Report of a New Procedure.
- Dr. James H. Mitchell, Chicago, The Streptococcal Infections of Skin and Mucous Membrane.
- Dr. Cecil S. O'Brien, Kansas City, Mo., Diagnosis and Treatment of the Three Major Complications of Mastoid Disease.
- Dr. Otto Jason Dixon, Iowa City, Tumors of the Orbit.

There will be round table discussions, alumni and fraternity dinners, a smoker Tuesday evening and a banquet Wednesday evening.

Congress of Physical Therapy.—The eighteenth annual session of the American Congress of Physical Therapy will be held at the Hotel Pennsylvania, New York, September 5-8. The formal opening of the congress will take place Tuesday evening with addresses of welcome by Drs. Terry M. Townsend, New York, president of the Medical Society of the State of New York; Farel Jourard, New York, president, New York

Physical Therapy Society, and Benjamin Ulanski, Philadelphia, president, Pennsylvania Physical Therapy Association. Dr. William H. Schmidt, Philadelphia, will make his official address as president at this time on "The Future Development of Physical Therapy." Other speakers will include Drs. Bayard T. Horton and Frank H. Krusen, Rochester, Minn., on "An Evaluation of Methods and Mechanical Devices for Producing Increased Blood Flow in the Extremities"; Horatio B. Williams, New York, "Radio Interference by Electric Apparatus," and Russell L. Cecil, New York, "Physical Therapy as Compared with Other Forms of Therapy in Arthritis." The session on eye, ear, nose and throat will hold sessions Wednesday and Thursday. The general scientific session Thursday will be devoted to a symposium on fever therapy with the following speakers:

- Dr. Murray B. Ferderber, Pittsburgh, Recent Developments Resulting from Fever Therapy Research.
 - Drs. Walter M. Solomon and Robert M. Stecher, Cleveland, Artificial Fever in Chronic Atrophic Arthritis.
 - Dr. William K. Ishmael, Oklahoma City, Autochemotherapy Reinforced with Artificial Fever in Rheumatic Disease.
 - Dr. Herbert Worley Kendall, Dayton, Fever Therapy in Syphilis and Gonococcal Infections.
 - Drs. Arthur Elmer Belt and Alvin W. Folkenberg, Los Angeles, Treatment of Gonorrhea by Artificial Fever Alone and by Fever in Combination with Sulfanilamide.
 - Drs. Earl C. Elkins and Robert L. Bennett Jr., Rochester, Minn., A Laboratory Technic for the Production of Fever.
- The general scientific session Friday will be a symposium on fractures with the following speakers:
- Dr. Eldridge L. Eliason, Philadelphia, Fractures.
 - Dr. Henry Jordan, New York, After-Care of Fractures with Special Reference to Delayed Union and Sudeck's Atrophy.
 - Dr. John P. Stump, New York, Maintaining Reduction in Oblique Fractures of Long Bones.
 - Dr. Miland E. Knapp, Minneapolis, The Role of Physical Therapy in Fractures.
 - Dr. Philippe Bauwens, electrotherapist, St. Thomas's Hospital and Royal Westminster Ophthalmic Hospital, London, Present Status of Iontophoresis.
 - Dr. Harold A. Abramson, New York, Iontophoresis of Epinephrine in the Treatment of Severe Asthma.
- An instruction seminar will be held August 30-September 2 including lectures, hospital clinics and conferences.

FOREIGN

Congress on Electroradiology.—The fourth Congress of French-Speaking Electroradiologists will be held in Paris October 11-14 under the presidency of Dr. Louis Delherm. This congress was postponed from October 1938. Those who wish to attend should send applications as soon as possible to M. le Dr. Dariaux, secretary-general, 9 bis, Boulevard Rochechouart, Paris 9.

Congress on Plastic Surgery.—The fourth international congress under the auspices of the European Society of Struc-tive Surgery will be held in Paris October 5-7. Prof. Pierre Sebileau, Paris, is honorary president and Dr. Leon Dufour-mentel is president. The subjects chosen for discussion are treatment of deformities resulting from scar retractions of the eyelid and treatment of deformities of the jaw. Other communications will be strictly limited to subjects in plastic an-reconstructive surgery. For further information address the secretary of the congress, Maison de Chirurgie, 9 rue de Turin, Paris.

Prize Offered for Paper on Tuberculosis.—The International Union Against Tuberculosis offers the Leon Bernard Prize for 1940 of 2,500 French francs for the best paper submitted on "Conjugal Tuberculosis." The essays may be in English or French; they must be typewritten or printed and must not exceed 10,000 words. The award is available to governments and associations belonging to the union and papers should be forwarded by the member associations to the Secretariat of the International Union Against Tuberculosis, 66 Boulevard Saint-Michel, Paris, not later than May 1, 1940. Should the executive committee decide that no essay is of sufficient merit to receive the award, the prize will not be awarded in 1940 but will be offered again the next year.

CORRECTION

The Other Dr. Adams.—A news item under California in THE JOURNAL, August 5, page 516, announced that Dr. Burton W. Adams, Oakland, had been appointed superintendent of the San Diego County Hospital, San Diego. Dr. Burton W. Adams telegraphed that this should have been Dr. Burton A. Adams, San Leandro.

Annual Meeting of the British Medical Association

The 107th annual meeting of the British Medical Association was held at Aberdeen. The President, Dr. Thomas Fraser, took as a subject for his address "Forty Years of Practice." Much progress has been made in the matter of nutrition, which had been in the limelight since the war. There was now a greater variety of food, but practical knowledge of food values was still lacking in an important section of the population, which conduced to increasing use of canned and bottled foods, even when fresh food was available at more economical rates. But we consumed a larger quantity of dairy produce. If butter and cheese were counted as the equivalent of milk, our consumption of milk per head had risen from 73 gallons per head in the five year period 1925-1929 to 89 gallons in the 1925-1929 period—a figure higher than that in the United States and other European countries. The improvement in nutrition was reflected in the rates of infant mortality 55, maternal mortality 3.26, puerperal sepsis 0.98 and tuberculosis 56 of today, against 70, 4.11, 1.57 and 79 of 1927. The reports on the health and physique of the many thousands of young men recently called up for the militia were highly satisfactory.

The great service which the association had rendered to the nation was organizing of the profession as an effective force able to present its views to Parliament and the people. In doing so it had been instrumental in no small measure in directing the health policy of the country. Many committees submitted valuable reports on this, which after years of delay were taken up by the government and incorporated in legislation. Of these the medical inspection of school children had been of profound benefit because of the earlier recognition and treatment of ill health in children. But the government adopted it only after ten years of delay.

IMPROVEMENTS IN THE BRITISH MEDICAL JOURNAL

At the representative meeting Dr. R. G. Gordon, chairman of the Journal Committee, said that the new Key to Medical Literature had met with much appreciation. It contained more than twice the number of abstracts that its predecessor, the *Epitome*, did. An endeavor had been made to prepare for an emergency by interrupting the series of general practitioner articles by a special war series. With regard to the special journals published by the association, for the first time one had shown a credit. The *Journal of Neurology and Psychiatry* in new form had increased its subscription list. The *British Heart Journal* already had a subscription list of nearly 400. Arrangements had been made for a *Journal of Thoracic Medicine and Surgery*. One member was perturbed at the increasing cost of the *British Medical Journal*. He thought it ought to pay for itself, and one of the reasons why it did not was that it was much too large; the only people who could read it all were retired and semiretired practitioners! Dr. Gordon did not think it desirable to state how much of the members subscriptions went to the *Journal*. No such periodical could meet all its expenditure from its own revenue, and the American Medical Association allotted more than half its revenue to its journal, while the proportion for the *British Medical Journal* was less than one sixth.

EMERGENCY ORGANIZATION

Sir Kaye Le Fleming, chairman of the Central Emergency Committee, said that in the emergency of last September the profession had made a magnificent response and there was a register of 96 per cent. The Ministry of Health coordinated all requests from the fighting services for medical personnel

and these were supplied through the Central Emergency Committee. In any emergency the first demand would be for the civil defense of the country, and the ministry had set up an organization in various parts to deal with possible eventualities. In every area there would be a local emergency committee to represent medical interests. No physician would be allocated to any special duty except through it. An agreement had been come to with the government on the civil hospital emergency service that the scale of remuneration would correspond to that of the army. The payment for part time services had also been agreed on.

RECOGNITION OF LAY PSYCHOTHERAPISTS REFUSED

The council was defeated on its recommendation for recognition of lay therapists, including the clergy, under certain conditions. These were that no one should undertake treatment except on the recommendation of a physician or after investigation of the case by one; also no physician should recommend a patient to lay psychotherapists without being himself a specialist in psychologic medicine or without assuring himself that the lay therapist was adequately trained. In the discussion one member said that the peculiar position of the clergy made them quite unfit to act as psychotherapists. In supporting the recommendation the chairman asked, Was it advisable that clergy, working in conjunction with and to some extent under the control of the medical profession, should have some training in psychotherapy, and was it desirable that the large body of lay psychotherapists already practicing should be allowed to work without any control by the medical profession? The recommendation was defeated by 102 votes to 75.

THE ADMINISTRATION OF ANESTHETICS BY MIDWIVES

A recommendation by the council was moved that a state certified midwife may administer nitrous oxide and air by an approved apparatus as an anesthetic in labor, provided (1) that she has received at an approved institution instruction in the essentials of obstetric analgesia and has shown that she is thoroughly efficient in the use of the apparatus, (2) that the patient has within one month of her confinement been examined by a registered medical practitioner who has handed to the midwife a certificate that she is in a fit state for the administration and (3) that one other person, being a certified midwife, registered nurse or senior medical student is present. It was pointed out that for some time midwives had been administering anesthetics and that this had been approved by the Royal College of Obstetricians. The motion was defeated by a large majority.

AN APPROVED LIST OF PROPRIETARY MEDICINES ABANDONED

The council announced a reluctant conclusion on financial grounds to abandon the establishment of an approved list of proprietary medicines. A draft scheme had been prepared by a conference with the Pharmaceutical Society. It was stated that \$10,000 would be spent on an investigation and probably more later, having regard to the experience of the American Medical Association, which spent \$55,000 a year. The joint conference had great difficulty in limiting the sphere of its investigations, because many millions of pounds was spent on secret remedies. While the conference admitted the working of the American scheme, it was said that no country was more ridden by proprietary articles than America. With the present commitments of the association they were unable to proceed but would be only too glad to take up the matter when circumstances allowed.

TREATMENT OF UNUNITED FRACTURES

In opening a discussion in the Section of Orthopedics and Fractures, Mr. Naughton Dunn said that, if a patient had delayed union or nonunion of a fracture and the Wassermann reaction was positive, antisiphilic treatment was necessary.

In cases of compound fracture the nature of previous infection should be investigated, so that the patient may be immunized by serums or vaccines before any operative procedure. Even in mild cases it was wise to wait six months after healing of the wound before operating, and it was safer to excise all scar tissue and remove any foreign body which might be present. Every effort should be made to restore the tone of the muscles and other tissues by massage, physical therapy and exercise. Cases complicated by a lesion of one of the main nerves were common in war surgery but were seldom seen in peace. When there was loss of one or more inches of nerve, suture should have priority to operation on bone, because recovery of the nerve takes longer than bone union, and the nonunion may allow end to end suture of the nerve not possible after continuity of the bone is established.

Mr. Dunn condemned active surgical treatment with introduction of foreign material. It had been responsible for many cases of nonunion. The records of Guy's Hospital showed that plating of fractures had lost favor in the home of its birth, and its tragedies were frequently seen in orthopedic hospitals. The question whether union of the fracture would improve function should receive careful consideration. In some cases it had the opposite effect. During the war it was found that, in nonunion of the lower end of the ulna with ankylosis of the inferior radio-ulnar joint, union of the ulna was a disadvantage. While the ulna was ununited, pronation and supination took place at the false joint but were lost after union. It was this that probably led Baldwin of San Francisco to produce a false joint in the lower third of the ulna when destruction of the inferior radio-ulnar joint interfered with pronation and supination. In some cases removal of the fragments gave the best functional result. For example, in old cases of nonunion of the patella and olecranon removal of the bone and reestablishment of continuity of the extensor apparatus was the best method of relieving pain and improving function. In cases of pain associated with nonunion of the internal malleolus, removal of the fragment was preferable to union. A gap in the continuity of the long bones could be bridged successfully only by an autogenous graft, as by the method of Albee. But where there was nonunion without loss of bone, a graft was not necessary. The ends of the bones should be exposed and freshened not by the usual subperiosteal method but by removal of cortical bone with its periosteum and muscular attachments. This left freshened bone surfaces which could be approximated and islands of living bone which, when sutured in relation to the joint, increased the area of living bone contact.

PARIS

(From Our Regular Correspondent)

July 8, 1939.

Status of the Profession in the French Colonies

The vast extent of the French colonial empire, the second largest in the world, creates problems of great scope and, at the same time, of great variety because of the difference in races and climates, although French colonial possessions are generally situated in similar tropical regions. The principle of cooperation with the native populations is, in general, observed but has not always given good results. Four institutions, situated at Bordeaux, Lyons, Brest and Marseilles, offer special instruction to physicians who intend to prepare themselves for service in the colonies. In Paris the Institute of Colonial Medicine also confers special medical diplomas. The medical education required of all physicians is a prerequisite to the special diploma for colonial service. In the colonies, notably at Hanoi in Indo-China, at Dakar in Senegal and in Madagascar, schools of medicine have been organized to train native physicians. The practice of medicine in the French colonies is subject to the same laws as in the metropolis. The medical diploma conferred on natives who have passed the examinations

in their local schools gives them the right to practice among the natives and to cooperate with organizations of preventive medicine and hygiene. There are five classes of physicians in the French colonies: native physicians, or, rather, native assistant physicians; physicians attached to colonial troops, who do not have the right to practice medicine among civilians in the metropolis but may do so in the colonies; other isolated military physicians sent by the government to regions without medical service; physicians in civilian life under contract with the colonial government, and finally physicians in private practice. From all of these five classes, but especially from army and navy physicians, the colonial governments choose the numerous personnel charged with the care of health and sanitation. One must add to this fivefold classification physicians drawn mostly from the army and navy who work in health centers such as the local Pasteur institutes and rarely have civilian clients. For the care of the needy, physicians are selected competitively. They give their whole time to their duties at times under primitive conditions, for they have charge of populations scattered over large areas deficient in means of communication and medical resources. Practicing physicians are naturally established in large cities, where they enjoy a fairly competent income. Many teachers of local medical schools also organize a private practice. Laws have improved the situation of French physicians practicing in the colonies by establishing the respective rights of civilian, army, navy and native doctors. But much needs to be done in matters pertaining to medical education. Notably the native physicians, in whom great hopes had been placed in the name of equality among men, have manifested little interest in acquiring the moral qualities without which medicine is not possible. Eager for profit, vain and revolutionary, they have revealed their complete inadequacy. The 740 colonial medical assistants, the 400 midwives and the thirty-six dentists trained by the School of Medicine at Tananarive, Madagascar, have failed to do what was expected of them; on the contrary, many of them have engaged in anti-French political activities. It will take a long time before these native physicians will acquire an honorable and sure position in the colonies. The situation is different in northern Africa. There are very good native physicians in Algeria. Morocco and Tunis because of their political status as protectorates are also open to physicians who are not Frenchmen. Many Russian émigrés, German Jews and other victims of the recent civil wars have established themselves there.

Masculinizing Properties of Human Urine

Binet and Luxembourg have reported to the Medical Society of the Hospitals of Paris ingenious experiments made on fish. Binet sought to find out whether fish could be utilized for detecting the hormone in male urine. For this purpose he employed the xiphophore, a pretty aquarium fish the male of which has a tail resembling a sword. Spontaneous sex mutations had previously been observed in these fish. Sex mutation had also previously been brought about by introducing testosterone propionate into the organ of female xiphophores. Females so treated were able to impregnate other females. The urine extract which Binet used was obtained by the Buthenault method. This consists in acidifying the urine by hydrochloric acid and then by preparing from it an extract by boiling chloroform, by dissolving in an ether and finally in oil. Intraperitoneal injections were made twice a week for six weeks on adult females. Toward the end of the fourth week bodily changes appeared followed by the characteristic male caudal fin. This proves that the male urine of human beings contains a substance capable of inducing the change from female into male. Xiphophore female fish treated with an extract prepared from female urine produced no alterations of somatic characteristics. The xiphophore may therefore be considered an excellent test for the study of the androgen in human urine.

Control of Prostitution in Lyons

The question whether prostitutes ought to be allowed their individual liberty or be deprived of it continues to attract much attention. Sociologists, in the name of universal principles, assert the rights of these women, but they do not seem to weigh the realities of the situation, for a syphilitic prostitute can infect hundreds of imprudent men. Ignoring the arguments that can be advanced against police surveillance, Lacassagne in the *Siècle médical* discusses the control system practiced in Lyons, the third largest city in France, with 600,000 inhabitants. Before 1905, police control was confined to house visitations or to women arrested on the streets charged with soliciting. No organizations existed for their medical care and education in the use of prophylactics. In 1905, changes were made. Every prostitute is now supplied with a health book in which are recorded the results of the inspections to which she must submit under penalty of arrest. It is in this situation that logic favors the opponents of control. They reason that in reality a citizen of a free country is imprisoned whose only crime is that she makes use of her body as she chooses, while the man who encourages her remains free, even though he has been the carrier of a virulent infection. The proponents of control reply that a syphilitic woman who can contaminate a great number of men is much more dangerous and culpable than a transient individual. Lacassagne cites experiences during the World War. Cases of venereal disease multiplied to such an extent in the French army that the military authorities had to institute a severe control of infected women. It is likely that the speculative Rights of Man and citizens' rights were violated. Doesn't the same situation prevail with regard to other serious diseases, such as leprosy and in public protection against narcotics? Lacassagne points out that prophylactic dispensaries, such as exist in Lyons, are also educational centers protecting both the infected prostitute and her patron by extending medical aid to her and showing him how to escape infection. According to the author, supervision of prostitutes is not only a legitimate exercise of police power but desirable for the prostitutes themselves. In Grenoble, a town in southern France where prostitution is not under surveillance, prostitutes are nevertheless arrested when plying their trade. The next day they are set free without regard to their infection. There can be no doubt that the Lyons plan is the better plan. He asserts that because of the measures in force in Lyons clandestine prostitution, which certainly is the most dangerous of all, is of infrequent occurrence. A well organized police control acts as a constant check. Like many other human institutions, regulation of prostitution is no better than the men charged with enforcing it: the physicians, the police and other officials.

BELGIUM

(From Our Regular Correspondent)

July 5, 1939.

Regulations to Protect the Health of Employees

General regulations affecting the health of employees have just been issued applicable to industrial establishments and public service establishments, including public utilities. It is prohibited to use damp or unhealthful premises as offices. Offices must be separated from workshops or store-rooms in such a manner that employees are protected as much as possible against noise, vibrations, heat and noxious odors. Precautions must be taken to avoid fire hazards. The premises must be easily accessible at all times so as to assure the safety of the workers in case of fire. Where necessary, provision must be made for the rapid rescue of the employees by means of fire escapes and special exits. It is prohibited to store inflammable or explosive materials in offices. Every office employee must have working space amounting to 10 cubic meters and a surface area of at least 4 square meters. The distance to the

ceiling from the floor must not be less than 2.5 meters. The floor of the premises must constitute an even surface without cracks and must be constantly kept clean. Premises must be ventilated completely at least once a day outside working hours. Offices must be suitably lighted. During the day they must receive sufficient natural light, preferably by means of illuminating surfaces that allow the sunlight to enter directly. As far as possible, lighting surfaces should include windows in outside walls. Provision must also be made for the protection of employees against direct sunlight. In winter, the temperature must be maintained between about 18 and 22 C. (64 and 75 F.) and controllable by easily accessible apparatus. The humidity must conform to hygrometric standards. Heating apparatus must be supplied with equipment permitting regular elimination of gas caused by combustion. Chimney drafts may not be controlled by contrivances that may completely shut off gas elimination. Rooms set apart for the use of employees must be cleaned by processes that do not raise the dust. Thorough cleaning must be done at least once a week. Notices must be posted forbidding expectoration on the floor. Office employees must be provided with seats that have backs permitting them to rest their feet on the floor or flatwise on raised supports. There must be at least one toilet for twenty-five male persons and one for fifteen female persons. The toilets must be kept in a good, clean condition. Owners, managers and directors are required to place at the disposal of their employees the necessary means (1) of changing their street clothes under conditions of hygienic safety and suitable decency, (2) of washing their hands and face and (3) of taking their meals under satisfactory conditions of health and comfort. Owners, managers and directors of establishments are required to take the necessary measures, in case of accidents or grave illnesses, for arranging first aid, as well as transportation of the patient either to her home or to a place where she may receive prompt attention. Whenever the establishment has at least ten employees the means of first aid, always kept in perfect condition and for immediate use, should consist at the least of a medicine chest corresponding to the conditions set forth. Employees are forbidden to take their meals elsewhere than at the places designated, to lay down their clothes outside the places appropriated for such use and to bring alcoholic beverages into the offices, store-rooms or buildings. Employees at work at open air counters connected with bazaars and stockrooms may not be employed at such work more than four hours a day in two hour shifts with an interval of at least one hour. Nor may they work after 7 p. m. or when the temperature is lower than 5 C. (41 F.). They must be protected against rain, wind and air currents and against direct sunlight by means of top covers. Heating arrangements must be made for them from October 15 to April 15 when the temperature is below 10 C. (50 F.) or else opportunities be given for periodic warmings.

The Control of Milk and Butter Production

An official licensing system for the control of the production and sale of milk has been set up in order to promote improvement in quality. To be licensed, the producers must establish to the satisfaction of the veterinary inspector that their stables, cows and methods of production correspond to the following general directions: Milk cows must be free from mastitis and their condition of health compatible with the production of a wholesome normal milk. Their maintenance with regard to cleanliness must be perfect. The stable ought to contain only cows to the exclusion of calves. The use of fodder and drinking water that might affect the quality of the milk unfavorably is prohibited. Milking must be done into irreproachably clean utensils by careful milkers. The milk must be filtered and rapidly cooled. Receptacles used for delivery must be of one piece, beaten out or welded. If they are plated, the plating

must be without defects. They must be handled in such a way as to avoid the risk of injury. Similar control provisions are applicable to the production and sale of butter.

The Queen Elizabeth Foundation in the Congo

The Queen Elizabeth Foundation aims to discover, by means of biennial examinations of the whole population of the Congo, the diseases likely to make themselves felt in the demographic statistics and to furnish treatment in the dispensaries to those in need of it. The foundation is also engaged in social work such as infant welfare, maternity and antepartum service and the sanitation of villages. For the medical work among the natives of the Belgian Congo the foundation has an important administrative personnel: one medical head, twenty-five assistant physicians, twenty-one European health officers and numerous native helpers. A quadrennial plan (1939-1942) has been established for the construction of buildings necessary to house personnel, services and the handling of the many indications for the rapid assignment of the personnel. A total of 300,000 vaccinations was performed in 1937. The decrease in the number of persons stricken with trypanosomiasis has been all the more rapid as the living conditions have become more favorable.

AUSTRALIA

(From Our Regular Correspondent)

July 4, 1939.

Expenditure on Alcohol

The consumption of alcoholic liquor in New South Wales last year was such as to cost a community of 2,718,000 people nearly £16,000,000. This total showed a sharp increase over the previous year. The drink bill last year exceeded by some £3,000,000 the total state outlay during 1937-1938 on education, social services and health.

Modify Stand on Social Security Act

Two radical departures from the previous attitude of the British Medical Association in New Zealand toward the maternity benefit scheme under the Social Security Act are revealed in a circular issued to all members. It is now suggested that fixed medical fees be provided for normal cases but that variation of payments be made when abnormalities are encountered and that fees payable from the security fund be paid direct to the doctor. The association has thereby abandoned its claim for a cash payment to the patient. The circular suggests that the government will be asked to amend the act to give effect to these proposals, which will mean that all doctors doing maternity work will be compelled to enter the scheme.

A Medical Paradox

A paradox of doctors presents itself in New South Wales. Professor Windeyer, dean of the Faculty of Medicine at Sydney University, declared that the number of medical students should be limited, since for some years to come the supply of doctors in Australia would be greater than the demand for their services. On the other hand, country hospitals and districts are unable to secure medical practitioners even though the state government provides a guaranteed income of £500 a year in addition to private fees. The government is considering the filling of the breach by "regional registration" of refugee doctors. The British Medical Association contends that a government subsidy of £1,000 should be provided for doctors in outback districts. Critics of this statement draw attention to the fact that not 50 per cent of the solicitors in the state are earning the despised £500 a year, while more than half of the barristers are making a lesser income. Even more pertinent are the deplorably low earnings of qualified engineers, although their profession may be regarded as highly skilled—and as socially valuable—as that

of the doctors. It would appear in fact that the medical profession tends to demand—and expect—for all its practitioners standards of remuneration and of amenities which are not enjoyed by any but the more experienced and successful members of the other professions. The answer of the British Medical Association to this comment is that the guaranteed income of £500 is quite inadequate to enable a practitioner in sparsely populated areas to meet the professional expenses incurred in running his practice. Moreover the isolation and the absence of ready professional assistance, together with the greater responsibility thereby entailed, require an experienced practitioner whom the paucity of the subsidy must necessarily fail to attract.

ITALY

(From Our Regular Correspondent)

July 15, 1939.

Bassini's Operation for Hernia

Professor Catterina of Rome University recently lectured to physicians of the garrison at Rome on Bassini's radical operation for hernia. Catterina, who was a pupil of Bassini, said that the operation is of social importance. The frequency of hernia is more than 15 per cent in workers in some industries. Bassini performed the operation for the first time in 1884. He presented the first scientific report in 1886 and published his monograph in 1889. The monograph had some defects both in the text and in the illustrations from which the technic was erroneously interpreted and modifications were offered. Professor Catterina published a complete textbook on the operation with sixteen illustrations which were done by the painter Gaigher. The book was published in five different languages. The speaker reviewed the anatomic-physiologic principles of Bassini's operation. Bassini believed that the fascia transversalis is not the posterior aponeurosis of the transverse muscle. It is a membrane of varying thickness in different persons which originates at the small pelvis and goes over and behind the transverse muscle to the costal arches. Near the deep epigastric vessels it becomes thickened, enters the inguinal ring and, in the form of a sheath of common fascia, covers the inguinal cord and protects it during its passage through the inguinal canal. The region of Hesselbach's triangle is occupied by the caudal, fine aponeuroses of the transverse and small oblique muscles which identify themselves with the fascia transversalis and form the bottom of the triangle. Bassini's operation is based on the principle of providing the inguinal canal with a posterior wall which is made up of the fascia transversalis and the transverse and small oblique muscles. As a result of intra-abdominal pressure the muscles stretch in a special manner after the operation, because of the different course of their fibers, and prevent contact between the abdominal viscera and the inguinal cord and the compression of the former on the latter which was taking place before the operation was performed.

Petrification of Anatomic Specimens

Prof. Francesco Spirito, head of the obstetric and gynecologic clinic of Siena University, gave a lecture before the Accademia dei fisiocritici di Siena on a method of petrification of anatomic specimens. Positive results in petrifying anatomic specimens were previously obtained by Segato, Gorini and Marini but they never disclosed the method. Professor Spirito presented the specimens of the structures of the human body which were petrified by his method. He delivered the formula of his method of petrification to the Accademia dei Lincei, as he is attempting to improve the method before publishing a description of it. By means of Spirito's method it is possible first to petrify organs for studies on the external aspect of a given lesion (without resorting to artificial models, photographs or designs) and then to depetrify them for microscopic study. The procedure does not cause histologic

alterations of the organs. The cells retain the property of taking nuclear and protoplasmic stains for a long time. In the practical demonstration which followed the lecture the speaker showed the degree of petrification which the anatomic specimens acquire by his method. He presented a piece of marble united with petrified specimens of viscera. This part of the work is analogous to that which Segato carried on by doing a table with a mosaic which contains 214 anatomic specimens of human viscera which look like pieces of marble of various colors. Segato's table is preserved in a museum.

Care of Mothers

Laws have been provided recently for the care of working mothers. During the sixth month of pregnancy a medical certificate is given to the employer showing the approximate date of delivery. If the prospective mother wishes to remain at work up to three weeks before delivery, the employer will be given a medical certificate stating that the woman is in good health and can follow working without any possible danger for her health or that of the baby. When a woman asks to resume work at the end of three weeks after delivery (without waiting for the six weeks which is ordered by the law) the employer will ask her for a medical certificate showing that she is in good health. A woman may be absent from work in temporary illness during the course of pregnancy and the puerperium and also in case of either spontaneous or therapeutic abortion but in all cases she will give to the employer a medical certificate justifying her absence from work. Physicians will report abortion independently of having given the woman a certificate for her employer. When a woman leaves work for reasons related to pregnancy or the puerperium the employer will give her her social insurance card and a certificate with the date on which she started work and the date and cause of stopping work. Employers breaking the laws will be fined a given amount from 50 to 500 lire (\$2.50 to \$25) for each infraction.

Sanatorium for University Teachers and Students

The federal council of Switzerland recently invited the Italian government to cooperate in the foundation of an international sanatorium which will be built and organized in Leysin for teachers and students from universities. There is already at Leysin a sanatorium of the type, which has fifty beds and in which more than 700 persons from forty-two states, who are either teachers or students, have been cared for. The new international sanatorium will have 200 beds. The federal chamber of Switzerland made an allowance of 500,000 Swiss francs. The municipality of Leysin donated the grounds. The International League of the Red Cross and other organizations have made donations. Cash will be given in the form of donations for beds, each of which is evaluated at about 25,000 Swiss francs.

MADRID

July 25, 1939.

[NOTE.—In the July 8 issue of THE JOURNAL a letter from Madrid from our regular correspondent was published. He had not carried on his correspondence during the period of the civil war. A number of letters have been received protesting some of the statements made in this letter. The following letter was prepared in part by three former professors of Spanish universities who are now in exile.—Ed.]

Many of the statements in the Madrid letter from the regular correspondent of THE JOURNAL are inaccurate or give a false picture of the state of affairs during the late civil war in Spain. Although it is true that the office of "responsible" was created in Madrid at the beginning of the war, the medical profession of the Madrid hospitals was not under the direction of these officers. Even though rarely they may have exceeded their duties, they never took any important forcible actions on physi-

cians. The statement that the "responsible" of the hospital of San Juan de Dios was "a laborer at the Oporto port and knew but little Spanish" is contrary to fact, and the dermatologist mentioned in the regular correspondent's letter had been provisionally appointed president of the College of Physicians during the first phase of the war. His efforts, like those of other physicians on the board of directors of the college, were directed toward minimizing dangers to which politically opposed physicians might be exposed because of their hostility to the prevailing Republican government.

The identifying bracelets or "brassards" distributed at the onset of the war were intended to facilitate free passage for doctors. Soon, however, counterfeit brassards, attached to non-medical persons, began to circulate and it was considered necessary to register the arm bands and to furnish them with an official seal. This measure was adopted for all physicians regardless of political opinion. With regard to the expulsion of anti-Republican physicians from the Beneficencia Provincial in Madrid, this was ordered by the Board of Supervisors and not by the doctors, who, regardless of party affiliation, attempted to defend their colleagues against expulsion.

Dr. Gomez Ulla, referred to in the regular correspondent's letter, was a colonel in the army medical corps and was detained as he was deserting across one of the fronts. In spite of the customary punishment for this military offense, he was later exchanged for Dr. Jose Bago.

The Medical Syndicate of Madrid constantly gave instructions permitting any doctor to continue with his work during the war. Among the anti-Republicans treated in this way were Drs. Olivarez, Marañon, Gimenez Diaz, Rozabal, Viguera, Albosanz, Arredondo, Alvaro Gracia and Lopez Duran y Villa. Dr. Gimenez Diaz, professor at the Central University, was even furnished with a well equipped hospital in the suburbs of Madrid. Some of these physicians later left Spain without interference.

A number of prominent scientists and physicians were executed by the Nationalists, among them Dr. Sadi de Buen, Dr. Pablo Montañes, Dr. Eugenio Arbones, one of the best known gynecologists of Vigo, Dr. Vega Barrera, director of the hospital of Lugo, Dr. Telmo Bernardez de Redondela, Drs. Amancio Caamaño and Alejo Diz Jurado of Pontevedra, Dr. Dario Alvarez Limeses of Tuy, Dr. Jorge Etcheverri of Cangas de Morrazo, Dr. Vincente Varela Radio of Santiago, Dr. Luis Poza Pastrana of Pontevedra, Dr. Waldo Gil of Vigo, Dr. Jaime Quintenilla, Dr. Perez Carballa of El Farol and Dr. Baeza of Toledo.

As to the lack of food, the Madrid regular correspondent is quite accurate. In spite of the almost inconceivable shortage of food there was not a single epidemic—a fact which speaks well for the efficiency of the sanitary organization developed by the physicians.

Marriages

LEON STUART GORDON, Washington, D. C., to Miss Beryl Dorothea Jaffe of Birmingham, Ala., June 4.

WILLIAM CLEGG EVERSOLE, Vincent, Ala., to Miss Vivian Duncan Booker of Birmingham recently.

LE ROY M. ROBINS, Washington, D. C., to Miss Naomi Ellsberg of Raleigh, N. C., June 24.

WILLIAM P. GREGG, Drexel Hill, Pa., to Sarah Elizabeth High of Horsham, June 17.

THEODORE BURG RUSSELL, New York, to Miss Mary L. Peltz at Selkirk, June 24.

WILLIAM ARTHUR JOHNSON to Miss Ysobel Tyer, both of Uniontown, Pa., July 19.

ANTHONY H. GALLIS to Miss Frances Skundale, both of Atlanta, Ga., June 11.

ABE R. EVELOFF, Springfield, Ill., to Miss Vivian Grebler at St. Louis, July 13.

Deaths

Perry Bromberg ☉ Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1895; member of the House of Delegates of the American Medical Association, 1913-1915 and in 1917; secretary of the Tennessee State Medical Association, 1911-1914; past president of the Nashville Academy of Medicine and the Davidson County Medical Society; professor of clinical urology at the Vanderbilt University School of Medicine; formerly professor of urology at his alma mater; member of the Southeastern Surgical Congress and the American Urological Association; fellow of the American College of Surgeons; genito-urinary surgeon to the Vanderbilt University and St. Thomas hospitals; editor of the *Journal of the Tennessee State Medical Association*, 1911-1914; aged 64; died, July 4, of coronary thrombosis.

George Harold Ward, Blairstown, N. J.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1903; member of the Medical Society of New Jersey; at various times on the staffs of the Englewood (N. J.) Hospital, Manhattan Eye, Ear, Nose and Throat Hospital, New York, Holy Name Hospital, Teaneck, N. J., Nyack (N. Y.) Hospital, Hackensack (N. J.) Hospital, "Bergen Pines," Ridgewood, and the North Hudson Hospital, Weehawken; aged 59; died, May 30, of coronary thrombosis.

George Melick Boyd ☉ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1882; emeritus professor of obstetrics at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; fellow of the American College of Surgeons; served during the World War; consulting obstetrician to the Philadelphia General Hospital and the Preston Retreat; aged 77; died, May 20, in Ulster County, N. Y.

Walter Lowrie Campbell ☉ New Castle, Pa.; Jefferson Medical College of Philadelphia, 1903; past president and secretary of the Lawrence County Medical Society; served during the World War; at one time member of the city council and school board; aged 63; on the staff of the Jameson Memorial Hospital, where he died, May 29, of arteriosclerosis and hypertension.

Jacob Edgar Belville, Philadelphia; Jefferson Medical College of Philadelphia, 1882; Boston University School of Medicine, 1883; Hahnemann Medical College and Hospital of Philadelphia, 1901; professor emeritus of physiology at the Hahnemann Medical College and Hospital; aged 80; died, May 30, in the Hahnemann Hospital.

Fred Gordon La Rue, Lexington, Ky.; University of Louisville Medical Department, 1894; member of the American Psychiatric Association; formerly superintendent of the Eastern State Hospital, Lexington, and the Western State Hospital, Hopkinsville; aged 72; died, May 25, of hypostatic pneumonia and hypertensive heart disease.

Philip Allen Shinn, Rockland, Mass.; Tufts College Medical School, Boston, 1915; member of the Massachusetts Medical Society, American Psychiatric Association and the New England Society of Psychiatry; served during the World War; formerly connected with the U. S. Public Health Service, reserve; aged 53; died, May 23.

Ellis Edgar Willits Given, Ambler, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; served during the World War; fellow of the American College of Surgeons; aged 66; died, May 11, in the Pennsylvania Hospital, Philadelphia, of chronic adhesive pericarditis.

James Allen Fetherolf, Stockertown, Pa.; Jefferson Medical College of Philadelphia, 1880; Hahnemann Medical College and Hospital of Philadelphia, 1883; member of the Medical Society of the State of Pennsylvania; formerly county coroner; aged 81; died, May 3, in the Easton (Pa.) Hospital.

Joseph Leo Conarton, Mayfield, Pa.; College of Physicians and Surgeons, Baltimore, 1915; member of the Medical Society of the State of Pennsylvania; for many years school physician for the school district of Mayfield; on the staff of St. Joseph's Hospital, Carbondale; aged 55; died, May 21.

Samuel W. Price, Scarbro, W. Va.; University College of Medicine, Richmond, 1896; member of the West Virginia State Medical Association; past president of the Fayette County Medical Society; member of the Public Health Council; aged 68; died, May 31, of coronary thrombosis.

James Talmage Wyckoff, Leonia, N. J.; Long Island College Hospital, Brooklyn, 1893; veteran of the Spanish-American and World wars; aged 67; on the staff of the Engle-

wood (N. J.) Hospital, where he died, May 6, of coronary thrombosis and carcinoma of the prostate.

Charles R. Haman, Reading, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1891; member of the Medical Society of the State of Pennsylvania; on the staff of the Homeopathic Medical and Surgical Hospital; aged 71; died suddenly, May 29, of heart disease.

Walter Chafey Moodie ☉ Valhalla, N. Y.; University of Nebraska College of Medicine, Omaha, 1912; served during the World War; aged 56; on the staff of the White Plains (N. Y.) Hospital and St. Agnes Hospital, White Plains, where he died, May 7, of coronary thrombosis.

Thomas Arthur Flood, Los Angeles; Georgetown University School of Medicine, Washington, D. C., 1897; member of the Utah State Medical Association; formerly on the staff of the Holy Cross Hospital, Salt Lake City; served during the World War; aged 69; died, May 9.

Harry Alexander Simrell ☉ Stockton, Mo.; Bennett Medical College, Chicago, 1913; past president of the Vernon-Cedar Counties Medical Society; member of the state legislature; aged 52; died, May 22, in the Springfield (Mo.) Baptist Hospital of meningo-encephalitis.

Joseph Carl Kamp ☉ Casper, Wyo.; Denver and Gross College of Medicine, 1909; fellow of the American College of Physicians; formerly on the staff of the Memorial Hospital of Natrona County; aged 59; died, May 13, in the Scripps Memorial Hospital, San Diego.

Alpha Haven Harriman, Laconia, N. H.; Medical School of Maine, Portland, 1883; member and past president of the New Hampshire Medical Society; fellow of the American College of Surgeons; past president of the board of education; aged 81; died, May 29.

Charles Henry Brown ☉ Franklin, Pa.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; for many years health officer and member of the school board; on the staff of the Franklin Hospital; aged 62; died, May 12, of pneumonia.

Paul Kibbe Sellew ☉ Los Angeles; Yale University School of Medicine, New Haven, Conn., 1911; formerly professor of hygiene and pathology at the University of Southern California School of Medicine; served during the World War; aged 51; died, May 5.

William Tell Phillipy, Carlisle, Pa.; Jefferson Medical College of Philadelphia, 1884; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 76; on the staff of the Carlisle (Pa.) Hospital, where he died, May 9.

Charles Edward Holton, Washington, D. C.; University of Vermont College of Medicine, Burlington, 1892; for many years an investigator in the food and drug control division of the United States Department of Agriculture; aged 70; died, May 22.

Frederick Howard Dart, Niantic, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884; member of the Connecticut State Medical Society; aged 79; died, May 13, of chronic myocarditis and nephritis.

Francis C. Ferry, Los Angeles; University of Southern California School of Medicine, Los Angeles, 1903; member of the California Medical Association; served during the World War; aged 59; died, May 18, in the Veterans Administration Facility.

Milton Underwood McIntyre, Du Bois, Pa.; Baltimore Medical College, 1907; member of the Medical Society of the State of Pennsylvania; on the staffs of the Du Bois and Maple Avenue hospitals; aged 56; died, May 25, of coronary thrombosis.

Bertram Francis Alden ☉ San Francisco; Cooper Medical College, San Francisco, 1894; fellow of the American College of Surgeons; served during the World War; visiting surgeon to St. Francis and French hospitals; aged 66; died, May 14.

Russell Harrison Person, Athens, Pa.; Jefferson Medical College of Philadelphia, 1914; member of the Medical Society of the State of Pennsylvania; county coroner; on the staff of the Robert Packer Hospital, Sayre; aged 49; died, May 8.

David Edward Hoff ☉ Harrisburg, Pa.; University of Maryland School of Medicine, Baltimore, 1902; aged 64; on the staff of the Harrisburg Polyclinic Hospital, where he died, May 31, of left ventricular failure and cerebral embolism.

Levi Gilbert Ross, St. Helens, Ore.; Northwestern University Medical School, Chicago, 1907; member of the Oregon State Medical Society; county health officer; owner of St. Helens General Hospital; aged 59; died, May 30.

Henry H. Brundage, Bethesda, Md.; Fort Wayne (Ind.) College of Medicine, 1892; at one time mayor of Bloomville, Ohio; aged 79; died, May 5, in the Georgetown Hospital, Washington, D. C., of carcinoma of the stomach.

John Forney Rowan, Jacksonville, Ala.; University of Virginia Department of Medicine, Charlottesville, 1879; University of the City of New York Medical Department, 1880; formerly probate judge; aged 81; died, May 12.

Bertha Virginia Thomson, Oshkosh, Wis.; Northwestern University Woman's Medical School, Chicago, 1895; formerly city physician and health commissioner; aged 76; died, May 15, in the Mercy Hospital, of bronchopneumonia.

Joseph Thomas Ware, Starkville, Miss.; University of Nashville (Tenn.) Medical Department, 1890; formerly a member of the U. S. Public Health Service; aged 70; died, May 4, in the Mississippi Baptist Hospital, Jackson.

Harry Hiram Hewitt, Seattle; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; member of the Washington State Medical Association; served during the World War; aged 59; died, May 13.

Fred Rutan Underwood ♂ Seattle; Georgetown University School of Medicine, Washington, D. C., 1897; veteran of the Spanish-American War; aged 68; on the staff of the Providence Hospital, where he died, May 28.

Alvin Leonidas Jobe, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1914; member of the Arkansas Medical Society; served during the World War; aged 58; died, May 26, of myocarditis.

Wilfred Aloysius McKeough, Haydenville, Mass.; Tufts College Medical School, Boston, 1924; member of the Massachusetts Medical Society; on the staff of the Hampshire County Sanatorium; aged 47; died, May 26.

Bert Dutton George, Rochester, N. H.; University of Vermont College of Medicine, Burlington, 1896; member of the New Hampshire Medical Society; served during the World War; aged 66; died, May 21.

V. Leo Simones ♂ La Crosse, Wis.; St. Louis University School of Medicine, 1915; served during the World War; aged 47; died, May 7, in the St. Francis Hospital of chronic myocarditis and pulmonary edema.

Joseph Robinson Jones, Charleston, W. Va.; Howard University College of Medicine, Washington, D. C., 1923; served during the World War; aged 44; died, May 26, of acute dilatation of the heart.

Bern S. Schoenkerman, West Allis, Wis.; St. Louis College of Physicians and Surgeons, 1923; aged 54; died, May 18, at the Mount Sinai Hospital, Milwaukee, of injuries received in an automobile accident.

Roy De Lisle Wilson ♂ Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1908; served during the World War; aged 53; died, May 13, of a self-inflicted bullet wound.

William Stubenbord, New York; University of the City of New York Medical Department, 1879; member of the Medical Society of the State of New York; aged 86; died, May 23, of mesenteric thrombosis.

Albert Rubly Trapp ♂ Lincoln, Ill.; Rush Medical College, Chicago, 1901; served during the World War; aged 62; died, May 8, in St. John's Hospital, Springfield, of infection of the prostate and bladder.

William Robert Stephens, Toledo, Ohio; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1903; aged 62; died, May 28, in St. Vincent's Hospital of pneumonia and cerebral hemorrhage.

Joseph H. Gandy, Lipan, Texas (licensed in Texas, under the Act of 1907); member of the State Medical Association of Texas; on the staff of the Nazareth Hospital, Mineral Wells; aged 59; died, May 18.

James W. Ritter, Jersey Shore, Pa.; American Eclectic Medical College, Cincinnati, 1884; member of the Medical Society of the State of Pennsylvania; formerly bank president; aged 80; died, May 10.

Andrew John Bowman, Boise, Idaho; Jefferson Medical College of Philadelphia, 1916; on the staff of the Veterans Administration Facility; aged 61; died, May 1, in Hollywood, Calif., of heart disease.

Charles Allen Poage ♂ Colusa, Calif.; Cooper Medical College, San Francisco, 1901; past president of the Yolo-Colusa-Glenn Counties Medical Society; city and county physician; aged 65; died, May 2.

Albert Martin Reid, Vina, Ala.; University of Nashville (Tenn.) Medical Department, 1907; member of the Medical Association of the State of Alabama; aged 60; died, May 29, of diabetes mellitus.

Stuart John Thorson, Minneapolis; University of Minnesota Medical School, Minneapolis, 1924; aged 42; died, May 16, at the Northwestern Hospital of sarcoma of the left humerus and hemiplegia.

Benton Pulsifer Crocker, Foxboro, Mass.; Bellevue Hospital Medical College, New York, 1891; member of the Massachusetts Medical Society; aged 72; died, May 26, of coronary occlusion.

Sigmund Siegfried Lewandowski, Camden, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1927; aged 39; died, May 19, in the Hahnemann Hospital, Philadelphia.

Gifford Dean Wray Jr., Chicago; School of Medicine of the Division of Biological Sciences of the University of Chicago, 1939; aged 24; was found dead, May 2, of poison, self administered.

James W. McGrath, Hartland, Wis.; Milwaukee Medical College, 1910; aged 64; died, May 13, in St. Joseph's Hospital, Milwaukee, of lobar pneumonia and hypertrophy of the prostate.

W. B. Stewart, Georgetown, W. Va.; College of Physicians and Surgeons, Baltimore, 1905; aged 76; died, May 29, in the Fairmont (W. Va.) Hospital of intestinal obstruction.

Alvarez H. Smith, Brooklyn; University of the City of New York Medical Department, 1890; aged 73; died, May 22, in the Adelphi Hospital of gangrene and arteriosclerosis.

Joseph Kins Rowland, Flat Top, W. Va.; Medical College of Virginia, Richmond, 1926; aged 40; died, May 19, in the Raleigh General Hospital, Beckley, of acute encephalitis.

Eugene Arthur Redlinger, Dallas, Texas; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1895; aged 67; died suddenly, May 18, of coronary occlusion.

George F. Baier, Norwood Station, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1888; aged 79; died, May 7, of myocarditis and hypostatic pneumonia.

Charles Gaston Wilson, Clarksville, Tenn.; University of Michigan Homeopathic Medical School, Ann Arbor, 1882; aged 79; died, May 2, of influenza and pneumonia.

Albert Curtis Bond, Catlettsburg, Ky.; University of Louisville (Ky.) Medical Department, 1911; aged 54; died, May 7, in a hospital at Huntington, W. Va.

Thomas Stone ♂ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1883; aged 84; died, May 19.

Charles B. Weedman, Wellington, Ohio; Western Reserve University Medical Department, Cleveland, 1880; aged 81; died, May 10, of coronary thrombosis.

John F. Rousseau, Beckville, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1910; aged 66; died, May 17.

John Duncan Smith, Laurel, Miss.; Medical College of Alabama, Mobile, 1904; served during the World War; aged 66; died in May of heart disease.

William M. Boyd, Madison, Tenn. (licensed in Tennessee in 1889); aged 79; died, May 18, of fracture of the ribs resulting from a fall, and pneumonia.

William Ambrose Dower ♂ Windsor, Conn.; Tufts College Medical School, Boston, 1933; aged 34; died, May 13, in St. Francis Hospital, Hartford.

Thomas Owings Staples, Wylie, Texas; University of Louisville (Ky.) Medical Department, 1880; aged 78; died, May 18, of cardiac asthma.

Edward Everett Briry, Bath, Maine; Boston University School of Medicine, 1884; aged 80; died, May 28, of bronchopneumonia and influenza.

Ira E. Hall, Morgantown, W. Va.; Western Pennsylvania Medical College, Pittsburgh, 1892; aged 80; died, May 25, of uremia and myocarditis.

Lawrence Leonard, Londonderry, Vt.; University of Vermont College of Medicine, Burlington, 1918; aged 48; died, May 26, of myocarditis.

Charles Riley Laraway, Los Angeles; Northwestern University Medical School, Chicago, 1912; aged 62; died, May 31, of coronary thrombosis.

Ulysses S. Wasson ♂ Moorhead, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; aged 58; died, May 11, of coronary thrombosis.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Apostol Herb Tea.—Royal Mfg. Co., Duquesne, Pa. Composition: Essentially plant material including coriander seed, senna and bearberry leaves, and barks of licorice and cascara sagrada. Fraudulently represented as a remedy for dyspepsia, rheumatism, sick headaches and certain stomach, liver, kidney and blood disorders.—[N. J. 29049; December 1938.]

Balsam for Lungs.—Royal Mfg. Co., Duquesne, Pa. Composition: Essentially a syrupy liquid containing alcohol (about 5 per cent), water, chloroform, menthol, pine tar and extract of wild cherry bark. Fraudulently represented as effective in the treatment of simple ailments of the throat, chest and lungs, as well as whooping cough, asthma, croup, etc.—[N. J. 29049; December 1938.]

Betix.—Scheidemann Co., Milwaukee. Composition: Essentially a coarsely ground plant material consisting mainly of juniper wood, bark, needles and berries, and small amounts of bearberry and senna leaves. Fraudulently represented as a remedy for diabetes.—[N. J. 29050; December 1938.]

Bick's Mentholated Camphor Cream.—Bick Co., St. Louis. Composition: Small amounts of menthol and camphor, in a petrolatum base. Fraudulently represented as a remedy for catarrh, headache, sore throat, etc.—[N. J. 29041; December 1938.]

Bixlax Laxative Tonic Tablets.—Carnation Co., St. Louis. Composition: Extracts of plant drugs including a laxative and an alkaloid-bearing drug, such as belladonna, coated with sugar, iron oxide and chalk. Fraudulently represented as a "tonic" for stomach, liver, kidneys and bowels, and effective in blood and skin diseases, rheumatism, sick headache, etc.—[N. J. 29041; December 1938.]

Blue Ribbon Household Liniment.—National Blue Ribbon Remedy Co., St. Louis. Composition: Essentially turpentine, mineral oil and volatile oils including sassafras, and red pepper. For cramps, sciatica, pleurisy, corns, bunions, etc.—[N. J. 29041, December 1938.]

Elco Asthma Remedy.—Erie Laboratories, Cleveland. Composition: Chiefly sugar, water, potassium iodide and ephedrine sulfate. Fraudulently represented as an effective relief for hay fever, coughs, and certain forms of sinus trouble.—[N. J. 28368; September 1938.]

Elco Hepatic Tablets.—Erie Laboratories, Cleveland. Composition: Chiefly phenolphthalein, bile salts, emodin-bearing drugs and red pepper. For intestinal putrefaction, jaundice, gallstones, etc. Fraudulent therapeutic claims.—[N. J. 28368; September 1938.]

Erickson's Eczema Salve.—Dr. E. S. Erickson, Spring Grove, Minn. Composition: Essentially lead acetate and a camphoraceous oil incorporated in an ointment base. Fraudulent therapeutic claims.—[N. J. 28373; September 1938.]

Green Mountain Stick Salve.—Mrs. A. H. Westfall, Roulette, Pa. Composition: Essentially rosin, wax and a small amount of copper chloride. Fraudulently represented as a remedy for pleurisy, rheumatism, lumbago, boils, blood poison, etc.—[N. J. 28979; November 1938.]

Kalo's Headache Powders.—Menthio Jell Co., Inc., Albert Lea, Minn. Composition: Chiefly acetanilid, caffeine, tartaric acid and sugar. Fraudulent therapeutic claims.—[N. J. 28686; November 1938.]

Kalo's Mentho Jell.—Menthio Jell Co., Inc., Albert Lea, Minn. Composition: Essentially a small amount of volatile oils including menthol and eucalyptol, in a petrolatum base. Fraudulently represented as a remedy for catarrh, hay fever, sore throat, etc.—[N. J. 28697; November 1938.]

Kampfmuehler's Rheumatic Treatment.—Kampfmuehler Rheumatic Remedy Co., Louisville, Ky. Composition: Chiefly water, ammonium iodine, sodium salicylate, plant extractives and a small amount of alcohol. Fraudulent therapeutic claims.—[N. J. 28680; November 1938.]

Kobros Tablets.—Royal Mfg. Co., Duquesne, Pa. Composition: Essentially aspirin (5 grains per tablet). Fraudulently represented as a remedy for rheumatism, la grippe, headache, dizziness, etc.—[N. J. 29049; December 1938.]

Kolorok.—Kolorok, Inc., Spokane. Composition: Essentially calcium sulfate with a small amount of calcium carbonate. Fraudulently represented as a remedy for "all conditions due to lack of lime in the system"—indigestion, acidosis, gastric ulcers, kidney and bladder troubles, rheumatism, skin ailments, etc.—[N. J. 28374; September 1938.]

Kotofom.—Kotofom Corporation of America, South Bend, Ind. Composition: Chiefly water, soap and a small amount of glycerin, with minute quantities of fluorescein and a perfume. Fraudulently represented as a cure for severe cases of dandruff.—[N. J. 28690; November 1938.]

Kroup Monia Salve.—W. D. Taylor & Co., Bessemer, Ala. Composition: Essentially petrolatum, with small amounts of eucalyptol, menthol, thymol, camphor and oil of turpentine. Fraudulently represented as a remedy for croup and pneumonia, bronchial troubles, catarrh, "piles," burns and inflamed surfaces.—[N. J. 28369; September 1938.]

Lacto-Cal.—Lacto-Cal Laboratories, Los Angeles. Essentially water, lactic acid, calcium lactate, a small amount of volatile acid, coloring, and small proportions of compounds of sodium, magnesium, chlorine and sulfur. Misbranded because it did not contain enough calcium to justify the name; misbranded, further, because fraudulently represented as a cure for rheumatic conditions, intestinal disorders, heart trouble, and many other things.—[N. J. 28699; November 1938.]

Lemke's (Dr.) Anti-Bilious Blood and Catarrh Powder.—Dr. H. C. Lemke Medicine Co., Chicago. Composition: Essentially ground plant material (including an emodin-bearing drug and an unidentified alkaloid), free sulfur, sugar, and iron and calcium compounds. Fraudulently represented as an effective treatment for catarrh, blood, stomach, liver, kidney and bowel ailments, asthma, etc.—[N. J. 29042; December 1938.]

Lemke's (Dr.) Golden Electric Liniment.—Dr. H. C. Lemke Medicine Co., Chicago. Composition: Essentially small amounts of ammonia, volatile oils including camphor, cloves and sassafras, with chloroform, ether, alcohol (64.2 per cent by volume) and water. Fraudulent therapeutic claims.—[N. J. 29042; December 1938.]

Linimentine.—Carnation Co., St. Louis. Composition: Essentially small amounts of camphor, oil of sassafras, wintergreen, menthol and oleoresin of red pepper, in a petrolatum base. Fraudulently represented as a remedy for rheumatism, lameness, neuralgia, etc.—[N. J. 29041; December 1938.]

Mentholated LaPuris Kerchiefs.—Sterilek Co., Inc., Brooklyn. Composition: Tissue paper impregnated with menthol. For hay fever, rose fever, sinus troubles, etc. Fraudulent therapeutic claims.—[N. J. 28701; November 1938.]

Merz-Ailium.—Merz & Co. Chemical Works, Inc., Newark, N. J. Composition: Essentially extracts of plant drugs including garlic and an alkaloid-bearing drug plant containing hydrastine, with alcohol, sugar and water, flavored with oil of clove. Fraudulently represented as a cure for intestinal catarrh, diarrhea, rheumatism, colics, etc.—[N. J. 28681; November 1938.]

Nux and Iron Tablets.—Keystone Laboratories, Memphis. Composition: Extracts of plant drugs including nux vomica, and compounds of iron, zinc and phosphorus, coated with chalk and sugar. Fraudulently represented as a remedy for "lost manhood," lack of iron in the blood, acute dyspepsia, nervousness, etc.—[N. J. 28743; November 1938.]

Omar Palmer's Famous Prescriptions.—Oto Remedies, Inc., Hurley, Mo. Composition: "No. 38" (a "tonic"), an arsenic compound, extracts of plant drugs including a laxative, with salicylic acid (0.1 per cent), alcohol (4.8 per cent) and water; "No. 47" (for kidney and bladder disorders), potassium acetate and a small amount of extracts of plant drugs including buchu and a saponin-bearing drug, alcohol (8.7 per cent), and water; "No. 53" (for sour stomach, heartburn, etc.), extracts of plant drugs including an alkaloidal drug and a small amount of volatile acid, such as acetic acid, alcohol (6.7 per cent), and water; "No. 61" (for various forms of rheumatism), sodium salicylate (5 per cent), extracts of plant drugs, alcohol (8.5 per cent) and water, colored with caramel and sweetened with saccharin; "No. 76" (for bronchial troubles), small amounts of guaiacol, menthol and extracts of plant drugs, alcohol (6.2 per cent), sugar and water; "No. 94" (for asthma), an arsenic compound, extracts of plant drugs including lobelia, alcohol and water; "Prescription Pile Ointment," sulfur (about 9 per cent), and iron sulfate (2.6 per cent), in a petrolatum base. Fraudulent therapeutic claims.—[N. J. 28700; November 1938.]

Poreen Ointment.—Keystone Laboratories, Memphis. Composition: Essentially perfumed petrolatum, with a small amount of red mercuric oxide. Fraudulently represented as a remedy for eczema and other skin eruptions.—[N. J. 28743; November 1938.]

Red Oil Liniment.—W. D. Taylor & Co., Bessemer, Ala. Composition: Essentially kerosene, red pepper and volatile oils including those of turpentine and sassafras. Fraudulent therapeutic claims.—[N. J. 28369; September 1938.]

R. L. D. Procon Tablets.—Erie Laboratories, Cleveland. Composition: Chiefly baking soda, hexamethylenetetramine and a very small amount of alkaloid. For bladder irritation, sleeplessness, nervousness, etc. Fraudulent therapeutic claims.—[N. J. 28368; September 1938.]

Salacatin Bell.—Hollings-Smith Co., Orangeburg, N. Y. Composition: Essentially acetanilid (2.7 grains per tablet), salicylates, baking soda and starch. Fraudulently represented as a remedy for febrile and uric acid conditions, rheumatism, neuralgia, fermentation, etc.—[N. J. 28691; November 1938.]

Sana-Sal.—Sana-Sal Distributing Co., New York. Composition: Essentially magnesium, calcium, sodium and potassium chlorides and bromides. Fraudulently represented as a bath for the treatment of rheumatism, arthritis, insomnia, poliomyelitis, skin and joint diseases.—[N. J. 28372; September 1938.]

Septomang Antiseptic Tablets.—Crescent-Kelvan Co., Philadelphia. Composition: Largely zinc sulfate, potassium permanganate, sodium borate, and volatile oils including wintergreen, thymol, eucalyptol and

menthol. Not antiseptic when used as directed; fraudulently represented as an antiseptic and effective vaginal douche in leukorrhea, gonorrhea, etc.—[N. J. 28742; November 1938.]

Venus Tea.—Maison Laboratories, Cleveland, and Venus Tea Co., New York. Composition: Essentially senna leaves with small amounts of bladderwrack, camomile flowers, calendula flowers, mint leaves, and couch grass. Misbranded because represented to be derived from roots or barks, which it was not, and to be a harmless and beneficial reducer, which it was not. Fraudulent therapeutic claims.—[N. J. 28365; September 1938.]

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INFANTILE "COLIC" AND PHENOBARBITAL

To the Editor:—An infant has so-called colic—frequently called hyper-tonicity of the intestinal tract. The infant's abdomen is almost always moderately distended; percussion elicits the presence of gas in the intestine; otherwise the physical examination is negative. The infant has been gaining well and increasing in length; the bowel habit is irregular but satisfactory. The infant has been kept on a carnation milk, water and karo formula, with 1 drachm (4 cc.) of elixir of phenobarbital before each feeding, which means seven times a day. The phenobarbital is efficacious in producing sleep in the infant (6 weeks of age) rather than permitting it to cry continually. However, this means a daily ingestion of approximately 1½ grains (0.12 Gm.) of phenobarbital. Will any deleterious effects result from this dosage for a period of from three to six weeks or is there any danger of barbiturate poisoning? Please advise as to the possibility of a vitamin B deficiency being an etiologic factor in such cases. I ascribe this condition to a general constitutional inadequacy, particularly of the intestinal tract, which will adjust itself as the infant grows older. If no dangers or deleterious effects can result from such dosage of phenobarbital in an infant 6 weeks old it is certainly justifiable to make an infant "dopy" and sleepy rather than allow it to cry continually.

M.D., Iowa.

ANSWER.—In order to give a reasonable answer to the question of whether this 6 weeks old infant should be given 1½ grains of elixir of phenobarbital daily to keep him from crying, it would be well to review the causes of colic and attempt to make a rational diagnosis. Colic and distention of the abdomen in a baby may be caused by dietary indiscretions such as over-feeding, too frequent feeding or excessive carbohydrates in the diet. Congenital abnormalities of the intestinal tract such as congenital hypertrophic pyloric stenosis, congenital duodenal bands, obstruction along the small intestine and malformation of the colon, not to overlook stenosis and fissures of the rectum and anus, may cause the symptoms noted. Constipation due to an improperly balanced diet, paralysis of the abdominal muscles, spinal cord lesion and milk idiosyncrasies are other conditions which could produce these symptoms.

As an aid to diagnosis, a careful history with special reference to the diet should be taken, a complete examination of the stools should be done and, finally, an x-ray examination of the intestinal tract might be undertaken. The rational handling of such a case would then depend on the diagnosis arrived at and would be a much saner procedure than putting the baby to sleep with phenobarbital. The total twenty-four hour dosage of phenobarbital, 1½ grains, is excessive for an infant of this age. While infants have a good tolerance to phenobarbital, nevertheless if this dosage should be kept up for some time poisoning might result. Furthermore, though actual poisoning might not occur, one should not forget that the barbitals have side actions. They may cause gastrointestinal flaccidity and reduced peristalsis, decreased intestinal absorption of dextrose, decreased consumption of sugar by skeletal muscles, decreased secretion of urine, alarming restlessness, paresis of the tongue, cyanosis and asphyxia, skin rashes, depression of the spinal cord and reflexes, blood destruction and anemia (The Side Actions of Barbitals, editorial, THE JOURNAL, Aug. 14, 1937, p. 508).

If the mother had suffered from any considerable degree of vitamin B deficiency in her pregnancy, both mother and infant would probably show some of the active signs of beriberi. What effect a suboptimal vitamin B intake in the mother's diet during pregnancy would have on the infant is problematic. Without an attempt at a correct diagnosis one could hardly agree that "it is certainly justifiable to make an infant 'dopy' and sleepy rather than allow it to cry continually."

POSSIBLE DERMATITIS FROM TETRACHLOROETHYLENE

To the Editor:—Recently I have encountered three cases of an erythematous cutaneous rash following the wearing of garments cleaned with tetrachloroethylene (perchloroethylene). Is this condition a clinical entity or is it one of individual sensitivity?

George W. McCormick, M.D., Staten Island, N. Y.

ANSWER.—As tetrachloroethylene (sometimes termed perchloroethylene), like trichloroethylene, is a skin defatting agent, dermatitis might be expected from it; few, if any, cases are reported in the literature, while cases caused by trichloroethylene have been reported.

Both tetrachloroethylene and trichloroethylene are described in the National Formulary and in New and Nonofficial Remedies, 1939. Tetrachloroethylene is used in medicine chiefly as an anthelmintic for the treatment of hookworm infestation. It is generally considered to be less toxic internally than carbon tetrachloride. Trichloroethylene is used chiefly as an anesthetic, particularly in the treatment of tic douloureux. Tetrachloroethylene has been used considerably of late years in the cleaning of fabrics. In order to determine whether or not tetrachloroethylene is irritating, the following procedure is indicated:

1. Make patch tests with a piece of the offending garment in order to make sure that it caused the dermatitis.
2. Make patch tests with a piece of gauze dipped in the actual cleaning solution obtained from the cleaner, first allowing the wet gauze to stand a sufficient length of time for all the cleaning fluid to evaporate.
3. Make patch tests with a piece of gauze dipped in pure unused tetrachloroethylene, first allowing it to evaporate to dryness.

A positive reaction to patch 2 will show that the cleaning solution contains a nonvolatile irritant; a negative reaction to patch 2 and a positive reaction to patch 1 shows that the fabric of the garment is the irritant. A positive reaction to patch 3 shows that the dermatitis is not caused by an impurity or contaminant of the cleaning fluid; a negative reaction to patch 3 and a positive reaction to patch 2 show that there is an impurity or contaminant in the cleaning fluid.

Patch tests should be performed on a control, first with a piece of the garment that actually caused the dermatitis. If the control gives a positive reaction, the garment contains a primary cutaneous irritant. If the control gives a negative reaction, it shows that the garment does not contain a primary cutaneous irritant. If this is the case, a patch test should be performed on the control with a piece of the offending garment from ten to fourteen days after the first patch test has been removed. A positive reaction at this time will show that there is a non-volatile sensitizer remaining on the garment.

ADMINISTRATION OF AMMONIUM CHLORIDE

To the Editor:—Is there any good reason why I should not expect the same expectorant action from the enteric coated tablet form of ammonium chloride as from a solution? If so, please amplify.

Manasseh Kamen, M.D., Brooklyn.

ANSWER.—The expectorant action of ammonium chloride is due partly to some direct central stimulation but mainly to a reflex from its irritant action on the stomach and to a lesser degree on the intestine. Thus it can be readily understood that a greater degree of expectorant action will be obtained from a solution of ammonium chloride than from an equivalent amount of enteric coated tablets. If enteric coated tablets are employed, a much larger dose will be necessary to obtain a comparable degree of expectorant action.

DISINFECTION OF MATTRESSES

To the Editor:—Please give me what information you can regarding the disinfection and sterilization of mattresses, both for bacteria and for vermin; also any special information along this line on the new latex mattresses.

M.D., Indiana.

ANSWER.—Sterilization in terms of heat rarely if ever can be carried out without deleterious effects on either cotton felt or horsehair mattresses; consequently that method of sterilization is not recommended. It is advised that such mattresses be incased in removable, washable muslin covers when in use. Disinfection to some degree may be effected by removing the covers and then brushing the entire surface of the mattress thoroughly with 2 per cent saponated solution of cresol or similar antiseptic agents and then airing it for two or three hours, preferably in the sun. Relative to the infestation of mattresses by vermin, it has been found that subjecting them to hydrocyanic acid gas in a closed vault for twenty-four hours kills all forms of animal life without harming the material in any degree. Caution must be exercised in the use of this chemical agent.

Latex mattresses are claimed by their nature to be moth and vermin proof. It has been reported that exposure to direct sunlight brings about the most definite and rapid deterioration of this type of mattress. Under these conditions the outside layers undergo discoloration and destruction. However, these mattresses can be sterilized by autoclaving them at a temperature of 240 F. for fifteen minutes and but a slight degree of deterioration occurs when this procedure is instituted. Also these mattresses can be placed in the large laundry wash wheels and handled in the same way as linen in the large extractors and driers with no bad results apparently. In addition it has been stated that human wastes, ordinary antiseptic solutions and medications, with the exception of oils, have no harmful effects on them.

SULFAPYRIDINE IN BACTERIAL ENDOCARDITIS

To the Editor:—A case of subacute bacterial endocarditis has gone undiagnosed for twelve weeks owing to the delayed occurrence of petechiae and the absence of a definite heart murmur. July 4, blood culture showed a growth of *Streptococcus viridans* by a reliable laboratory. The patient was placed on 1 Gm. of sulfapyridine every four hours for five doses and has since been receiving 3 Gm. every twenty-four hours. He is showing some mild gastric disturbances but nothing more. A white blood count, hemoglobin determination and urinalysis are done every day. The results have been within normal limits. There has been no elevation of temperature since eight hours after the drug was started. The literature leads me to believe that this drug is rather toxic and I want to use due caution. In the only two cases I have seen reported, by Ellis, there was no mention of the period of time over which it was given or the dosage. Has any one succeeded in curing these cases with this drug? Do you think that the larger dose of 3 Gm. every twenty-four hours should be continued as long as tolerated in the hope that the focus on the heart valves will be eradicated? What is the longest period of time over which this drug has been given and what was the dosage? Should it not be discontinued gradually in endocarditis as in the treatment of pneumonia?

M.D., Texas.

ANSWER.—Whitby (*Lancet* 2:1095 [Nov. 12] 1938) has reported that he observed two patients with subacute bacterial endocarditis in whom the administration of sulfapyridine prolonged life and brought about a general improvement. Ellis (*ibid.* 2:1521 [Dec. 31] 1938) has reported similar observations. Unpublished reports to date show that sulfapyridine as well as sulfanilamide may bring down the temperature and pulse for a considerable time in patients ill with subacute bacterial endocarditis.

Long and Bliss (The Clinical and Experimental Use of Sulfanilamide, Sulfapyridine and Allied Compounds, New York, Macmillan Company) have reported that they have observed "cures" in five of sixty patients ill with subacute bacterial endocarditis and treated with sulfanilamide. It is not an uncommon occurrence to note a prompt response in the temperature and pulse of such patients after the administration of either of these drugs. A fall in the number of colonies of *Streptococcus viridans* in the blood generally accompanies the decrease in fever, and the blood stream may even become sterile. In many instances after a shorter or longer period of time, however, the blood culture will become positive again and the clinical manifestations of the disease will reappear and progress in general, despite further drug therapy.

Because sulfanilamide or sulfapyridine inhibits the multiplication of *Streptococcus viridans* in blood cultures, all blood cultures should be held for at least twenty-eight days before being discarded as negative. There is no definite rule that can be applied to determine the length of time that one can safely administer sulfapyridine.

The common toxic manifestations of the drug such as fever, rash, hemolytic anemia and hematuria generally appear in the first two weeks of treatment with the drug. Granulocytopenia is generally a late toxic manifestation, frequently appearing between the seventeenth and the thirtieth day of treatment. If a patient does not show any toxic manifestations there is no reason why the drug cannot be continued indefinitely.

One patient is known who has been receiving sulfapyridine continuously for the past seven months without any signs of toxicity. It would seem that it would be possible to continue the drug indefinitely in the case under discussion.

Five negative blood cultures taken at weekly intervals should be had, if possible, before the drug is discontinued. As far as is known there are no reports of "cure" in subacute bacterial endocarditis following sulfapyridine therapy.

It might be best to continue the drug in smaller doses, say 1.5 Gm. a day for at least two months after the patient is up and around. Also if the patient should recover and at any time in the future had to have an operative procedure on the oropharynx, prophylactic sulfapyridine or sulfanilamide should be given before and after the operative procedure.

UNILATERAL ENLARGEMENT OF BREAST IN SMALL CHILD

To the Editor:—A girl aged 30 months is in perfect health in every way except that she has an enlarged breast on the left side. It is full, rounded and soft but there is no fluid. It is about the size of the breast of a 13 year old girl. There is no pain. It came on gradually in the last twelve months and is not now progressing in size. What is there to do for this patient?

M.D., North Dakota.

ANSWER.—Unilateral enlargement of the breast in a 30 months old girl is a rather rare and unusual condition, especially when it is considered that the enlargement has been taking place since the infant was 18 months old. More frequently unilateral enlargement of the breast occurs in children between the age of 8 and 18 years. The enlargement takes place in girls between the eighth and the twelfth year and in boys between the fourteenth and the eighteenth year. One or both breasts may be enlarged. This condition is known as puberty mastitis, or mastitis adolescentum.

Occasionally hypertrophy of the breasts in young infants is associated with precocious menstruation. This precocious puberty in girls is thought to be due to hyperactivity of the pituitary gland. Others attribute this premature sexual development to ovarian tumors. Occasionally, abnormal mammary development in young female infants is unassociated with other evidence of precocious development. Such an instance is illustrated by Fred J. Taussig (The Female Reproductive System, in Brennemann's Practice of Pediatrics, Hagerstown, Md., W. F. Prior Company, 1937, volume III, chapter 31, p. 27). Among the tumors of the breast in children, angioma and lipoma may occur at any age. Carcinoma and sarcoma have also been observed.

The enlarged breast in this young child should be examined periodically. There would seem to be only two courses of procedure. As long as the growth remains stationary and the enlarged breast is soft, frequent periodic observations would seem the wisest course to follow. Progression in the growth or the occurrence of axillary glands or of nodules in the breast indicative of a malignant condition would demand immediate complete surgical removal.

NARCOTIC ADDICTION

To the Editor:—Please advise me concerning the present day treatment of morphine addiction. Although realizing the inadequacy of any ambulatory form of therapy, this is what I am most interested in. Do you know anything about the present work on combining morphine with insulin and thus reducing the requirements? What is to be done with an addict who has on several occasions been institutionalized for long periods and still requires from two to four injections a day? The Harrison Narcotic Law demands that the patient be on a reduction, yet this in my experience is hopeless.

Ellis M. Markell, M.D., Harrison, N. Y.

ANSWER.—There are hundreds of so-called cures or treatments of morphine addiction, and they are ever being augmented. During 1930 in a small country like Denmark, Larsen (*Ugesk. f. læger.* 92:1199 [Dec. 18]) reported that ten new methods for the treatment of chronic morphinism were tried. The solution of the drug evil probably does not rest on the administration of any specific cure but rather on the removal, when possible, of the underlying causes for which the drug addiction is merely an expression. In most cases, as in chronic alcoholism, it is an escape mechanism.

The complete treatment of drug addiction comprises two distinct stages. First, disintoxication and, second, rehabilitation, and of these the latter is far more important as well as far more difficult. There are scores of methods which, when properly applied, may free the addict from his drug, but by what method can he be freed from himself and made willing to stand mental and physical stress such as hundreds and thousands of people endure without resorting to narcotic relief? By rehabilitation is meant a recreation of the personality, for it is only when this is done (when it can be done) that the possibility of relapse is eliminated.

The House of Delegates of the American Medical Association in 1924 urged that federal and state governments put an end to the ambulatory treatment of narcotic addiction, whether by private physicians or by clinics or dispensaries. Ambulatory treatment is discountenanced too by the U. S. Bureau of Narcotics. Unless carefully conducted, it may constitute a violation of law.

Therapeutically, insulin cannot replace or substitute for morphine. Hirsch (*Deutsche med. W'chenschr.* 54:1462 [Aug. 31] 1928) states that he found a low blood sugar value during withdrawal, and he gave injections of dextrose, which seemed to him to make his patients more comfortable.

Up to 1932 several writers reported good results using insulin with and without hypnotics in disintoxication treatment. How-

ever, the after-history of the insulin treatment is similar to that of most treatments which begin by being brilliant successes. A. G. Biggam and his colleagues (*Lancet* 1:922 [April 20] 1932) found the results extremely disappointing in twenty addicts treated according to this plan. Insulin is still occasionally employed with or without dextrose as part of a more general treatment. Kolb (*Hospital News*, Treasury Department, Washington, D. C., 1936) reports that it has fallen into disfavor.

Any addict who has had several successful denarcotization or disintoxication treatments and who has not an incurable, demonstrable disease that necessitates morphine for analgesic relief may have to be confined in a place where the drug is unobtainable and released only on probation as long as he abstains from narcotics.

URETHRAL STRICTURE

To the Editor:—For several years I have been dilating urethral strictures of gonorrheal origin in a patient who first came to me after a severe hemorrhage from a false passage by sound or filiform for intractable strictures of seven years' duration. He has linear strictures which respond well to dilatation by successive sounds from 15 F. up to 27 F. But dilatations with a Kollmann dilator cause a bad reaction in that contraction along the entire urethra recurs within two weeks so that he has difficulty in voiding, and passage of a No. 15 F. is difficult, the urethra giving a dry sensation of leather. Various medicaments, including thyroid extract for resorption of fibrous tissue, have been unsuccessfully tried, for after three or four weeks the channel again closes. Mixed coccic infection in the prostate was cleared by massage and sulfanilamide. The patient went to a prominent urologic clinic, where urography being normal he was advised to have internal urethrotomy by electrothermal cutting. I thought this might result in more scarring. Is there anything otherwise to be suggested?

M.D. Michigan.

ANSWER:—The localization of the stricture in the urethra is of great importance in its treatment. If the stricture is situated in the anterior portion of the urethra and recurs in spite of repeated thorough dilatation, it is best treated by means of internal urethrotomy with an electrothermal knife. An electro-urethrotome has been introduced by Riba, which has greatly reduced complications that formerly followed internal urethrotomy. Internal urethrotomy should be followed later on by thorough dilatation of the urethra. The use of sounds, gradually increasing in size to No. 30 F. or 32 F., would be preferable to those of smaller caliber.

If the stricture is situated in the posterior portion of the urethra, and particularly in the prostatic urethra, internal urethrotomy is usually contraindicated, although if skillfully employed the electro-urethrotome may also be of value in this area. Thorough and repeated dilatation of the constricted areas, increasing gradually to a caliber of 35 F., usually will overcome the constriction. In case constricting bands are found near the bladder neck, they may be removed best with a resectoscope.

Thyroid extract or any other substance used for the resorption of fibrous tissues has not proved to be satisfactory.

In case of prostatic infection it would be well to continue massage and the intermittent use of either sulfanilamide or neoprontosil.

REMOVAL OF CERUMEN FROM EAR

To the Editor:—I wish to know about a solution suitable for removing without instrumentation moderately firm cerumen from the ear canal. With use of applicators, curets, spoons and the like, the factor of trauma still is to be reckoned with, and, assuming an intact drum membrane, would it be safe to use wax solvents occasionally in rendering the canal clear? Substances considered were acetone, carbon tetrachloride, xylene and benzene. I know that carbon tetrachloride works *in vitro*, but it produces considerable bronchial irritation on inhalation and I feared it for that reason.

R. F. Chittenden, M.D., North Hollywood, Calif.

ANSWER:—There is no doubt that there are certain wax solvents which could be used in the ear to soften impacted and inspissated cerumen with a view to making removal of this substance easy. Applicators, curets and spoons are not the ideal method for the removal of the cerumen. A well made metal syringe with the tip properly inserted in an upward direction so that the stream of water may get behind the plug and push it outward gives the best results. Some little instrumentation may be necessary to achieve this objective, but it should be done under good lighting and gently.

As for the various substances mentioned, it is quite possible that some of them will work. One or two at least will be irritating to the skin. Worldwide usage seems to indicate that peroxide solutions and sodium bicarbonate 4 per cent suspended in glycerin are safe and efficient. It may be that several sessions will be required before all the cerumen can be removed, but patience in proceeding in this manner will give good results nearly every time.

UNUSUAL REACTION TO ANESTHETIC FOR TONSILLECTOMY

To the Editor:—I had a peculiar reaction on a patient this morning while doing a local tonsillectomy, one that I am unable to explain. The local anesthetic I used was a 1 per cent solution of metycaine with 5 drops of epinephrine hydrochloride (1:1,000) to the ounce of solution. I had made the injection on the right side and had completed one 3 cc. injection around the left tonsil when the patient suddenly became faint and complained of double vision. Her face was normal on the right side but on the left a deathlike pallor was present, extending to the midline of the forehead, nose and chin. There was no paralysis of the facial muscles. This condition lasted for about five minutes and cleared up with only the inhalation of aromatic spirit of ammonia. The tonsils were removed and the patient was put to bed; she made the usual recovery in about fifteen minutes. Can you give me an explanation as to what possibly occurred? The patient is a woman, aged 48.

Minor E. White, M.D., Kankakee, Ill.

ANSWER:—The experience noted is uncommon. A fairly thorough search of the literature relating to atypical accidents following local anesthesia for the tonsil operation for the last ten years revealed practically no reports of a similar nature.

Comparable experiences have been noted, however, by oral surgeons and others working in similar fields. Kuehns, as quoted by Fischer and Grossman (*Local Anesthesia in Dentistry*, Philadelphia, Lea & Febiger, 1933, p. 69), states that on an experience based on 3,000 injections, injury to the blood vessels occurred in a small percentage of instances depending on the location of the injection. He notes "characteristic zones of anemia of the face or mucous membrane without severe complications following" and he also gives pictures of anemic zones following injections. In one illustration of such a zone following injection into the maxillary tuberosity there is an area of anemia involving a good part of the face.

What happened in the instance cited is difficult to say, but perhaps the epinephrine affected the sympathetic nervous system or produced a constriction of the external carotid artery or its branches supplying the face by having the needle pass through the constrictor muscle on that side.

BLOOD GROUPING AND TRANSFUSIONS IN RABBITS

To the Editor:—I am preparing to do some work on bleeding of and transfusion of blood in rabbits and am wondering whether you could provide me with any information relative to the typing in these animals. Are they likely to show reactions if the types are not compatible, or are there any such types as yet worked out in the rabbit? Any collateral information on this subject will be appreciated.

Groesbeck Walsh, M.D., Fairfield, Ala.

ANSWER:—Isoagglutination does not occur when blood cells and serums of different normal rabbits are mixed. However, individual differences exist as far as the red cells are concerned—as many as five different agglutinogens having been identified (Levine, Philip, and Landsteiner, Karl: On Immune Isoagglutinins in Rabbits, *J. Immunol.* 17:559 [Dec.] 1929; *ibid.* 21:513 [Dec.] 1931; Fischer, W.: *Ztschr. f. Immunitätsforsch. u. exper. Therap.* 86:97 [Oct. 3] 1935). The existence of these agglutinogens was detected by injecting rabbits with the blood of other rabbits, whereupon immune isoagglutinins resulted provided the blood injected contained agglutinogens foreign to the rabbit receiving the blood. Two of the agglutinogens are particularly potent as antigens, so that antisera are most readily obtained against these. These agglutinogens, usually designated as H₁ and H₂, have been most thoroughly studied and determine four groups—O, H₁, H₂ and H₁H₂, analogous to the four human blood groups O, A, B and AB (Castle, W. E., and Keeler, C. E.: Blood Groups in Rabbits, *Proc. Nat. Acad. Sc.* 19:403-411 [April] 1933).

One would assume, accordingly, that the initial transfusion in rabbits would cause no reaction. If, however, immune isoagglutinins result from the first transfusion, a subsequent injection of incompatible blood could give rise to a reaction.

Incidentally, there are individual serologic differences of another sort in rabbits that should be mentioned, since they might conceivably give rise to reactions when large amounts of blood are transfused. Rabbits can be divided into two classes as follows: (1) those containing an antigen related to the human agglutinin A in their tissues and no natural anti-A agglutinin in their serum; (2) those lacking A antigen in their tissues but containing natural preformed anti-A agglutinins in their serum. The injection of a sufficient amount of blood from the latter sort of rabbit into the former type might therefore cause a reaction. For further details concerning the question of A antigens and antibodies in normal rabbits see:

Stuart, C. A.; Sawin, P. B.; Griffin, A. M., and Wheeler, K. M.: Group-Specific Agglutinins in Rabbit Serums for Human Cells. *J. Immunol.* 31:31 (July) 1936.

QUERIES AND MINOR NOTES

705

FIBROSITIS

To the Editor:—Is there a definite disease entity of fibrositis? If there is, how is it diagnosed? What is the etiology? What is the treatment? What is the prognosis? I have read a pamphlet library on the subject, but I thought maybe there was some information on the subject now that was not available then. By some it is supposed to be due to a streptococcus and I have often wondered whether sulfanilamide has been used for it.

M.D., Texas.

ANSWER:—Fibrositis is a term applied to a condition, not infrequently encountered, which is characterized by stiffness, pain and aching of the muscles and tendons in the region of joints without associated objective signs except in occasional cases in which there is a slight swelling of the midphalangeal joint. The patient may have such symptoms for years, yet he never shows any of the usual signs of rheumatoid arthritis such as constitutional symptoms, x-ray changes, an increased sedimentation rate and the like. The so-called fibrositic nodule is, according to some, pathognomonic of this particular disease syndrome. Until more pathologic data in this disease are available, the disease will continue to remain an obscure and bizarre one. Many cases of so-called fibrositis represent early cases of rheumatoid arthritis. Others might much better be labeled psychoneurotic rheumatism. It is difficult to make the diagnosis with absolute certainty. The treatment, particularly in the chronic cases, is at best unsatisfactory. Given an individual with such symptoms lasting for years, without any objective signs, x-ray or laboratory evidence favoring rheumatoid arthritis, the prognosis is probably good. Sulfanilamide has been tried without beneficial effects. Until some one makes a more thorough-going study of patients with such complaints, the condition called fibrositis will continue to remain obscure.

INFORMING CHILDREN OF THEIR ADOPTION

To the Editor:—I was asked an unusual question by one of my patients yesterday, and I am referring to you for help. This family has two adopted children, one 4 years old and a baby of 6 months. The question has come up on how best to tell these children that they are adopted and when and how it should be done. Could you give me any information on how best to handle this situation?

M.D., Iowa.

ANSWER:—It is usually considered advisable to inform adopted children of the fact that they are adopted as early as possible. Of course 4 years is not too young to do this. Young children so informed have no emotional reaction and grow up just as secure in their status as do other children. The common technic used is to tell them that whereas most of their friends had to be accepted, their foster parents picked them out and chose them from a group of children and liked them best. That usually pleases the child and helps break the ice. If such children are not told when they are young there always comes a time when some one outside the family tells them, and in such a situation later on in life it is likely to cause considerable emotional reaction.

IRRADIATION OF BLOOD FOR HEMOPHILIA

To the Editor:—There is a hospital in our city which is treating a variety of illness by irradiation of the patient's blood in a container with a quartz window by means of ultraviolet rays. The blood is then returned to the patient, 500 cc. being the usual quantity taken. One of my patients suffering from hemophilia states that he is being treated by this method and that his clotting time has been reduced from 30 minutes to 9 minutes. What is the status of this therapy? Is it on a sound basis? Has there been any experimental work done to prove its value? Is it useful in allergic conditions?

F. C. Lane, M.D., Pittsburgh.

ANSWER:—Undoubtedly the treatment of hemophilic blood described would shorten the coagulation time. Anything that disturbs the chemico-physical balance of the plasma will produce this effect. The clotting time of hemophilic blood outside the body can be reduced from 80 to 90 per cent by the use of heat alone, optimal temperature about 50 C. (122 F.). If the platelets of hemophilic blood are ruptured mechanically and returned to the blood it will clot in normal time. There is no reason to believe that this treatment would be lasting. It would be similar but probably less effective than transfusion. Transfusion would have the additional benefit of restoring blood volume, hemoglobin, cells and proteins which are usually needed during the bleeding phase of this disease. Usually when blood is drawn from a patient with hemophilia and reinjected deep into the muscles of the buttocks it has a tendency to reduce the coagulation time. Intramuscular injection of normal blood is more effective. During the time a patient with hemophilia is absorbing blood from a confined hemorrhage there is a tendency toward lower coagulation time.

This procedure of irradiating blood necessitates all the mechanical procedures of blood transfusion except typing and adds the step of irradiating. It probably has no advantage over transfusion and several drawbacks but might serve a useful purpose if the blood is of rare type or difficult to cross match.

FALLING EYELASHES

To the Editor:—Please advise me of the causes and treatment of falling eyelashes. The case I have in mind shows no evidence of a chronic blepharitis. Also, please give me some standard reference.

Preston S. Herring, M.D., Vicksburg, Miss.

ANSWER:—The usual cause of falling eyelashes is, of course, chronic blepharitis. In some cases, after the blepharitis is healed, patients develop the habit of pulling the lashes. Sometimes this becomes almost unconscious, so that they insist that they do not pull them, yet there is every reason to think that they do. There are occasional cases in which the hair on the scalp. If no blepharitis is apparent cause, like the value of treatment is doubtful except that the patients can sometimes be cautioned against pulling the lashes. Sometimes the use of a 3 per cent zinc oxide ointment hydrated in hydrous wool fat will lessen the itching that prompts people to pull the lashes.

CORNEAL SCARS

To the Editor:—I have a case of opacity of the cornea due to a foreign body which I removed. The patient has been treated with 5 per cent ethylmorphine hydrochloride for one month. Recently he was placed on a 10 per cent aqueous solution of ethylmorphine hydrochloride. He is improving. At this time the scar is about the size of three pinheads. How long does it take the usual case to clear up? Is there a more effective treatment?

M.D., New Mexico.

ANSWER:—The clearing of a corneal scar depends to a great extent on the depth to which the scar involves the cornea. If the opacity is anterior to Bowman's membrane, it will easily disappear in from one to three months, with or without treatment. But if the scar itself involves Bowman's membrane and the anterior corneal stroma the possibilities are that it will never disappear entirely. Microscopic traces can always be found. Clinically, the reduction in the size and density of the scar takes a period of from three months to several years and apparently is not much influenced by treatment.

VISUAL SCREENING TEST

To the Editor:—What is the accepted opinion on telebinocular vision tests in the case of truck drivers and mechanics? Can the test be accurately and safely evaluated by laymen or do all such tests require follow-up examinations by an ophthalmologist as to the determination of the relative well-being of the eye as well as to an application of the usual visual refraction tests? Under such circumstances would these tests provide usable information that could be obtained by the Snellen chart, together with color appreciation tests?

R. V. Hoffman, M.D., South Bend, Ind.

ANSWER:—Apparently, what is desired is a visual screening test to weed out those with deficient vision. There have been several series of such screenings with telebinocular tests compared to the standard Snellen tests, and apparently the telebinocular tests are only about 70 per cent reliable and require a follow-up examination by an ophthalmologist. The Snellen test appears to be more reliable in nonmedical hands and can be applied by an intelligent person after only a short period of training. Those with normal vision can be passed on safely and those with deficient vision put under the care of an ophthalmologist. A visual screening of truck drivers should include a color vision test by all means. The Ishihara test is simple and reliable and does not require professional interpretation.

HERNIA REPAIR IN BOY

To the Editor:—What method is best for repair of a hernia in a boy ten years old? Is the Bassini operation as suitable as other types?

M.D., Florida.

ANSWER:—The type of repair of a hernia in a boy 10 years old depends somewhat on the character of the hernia and its extent. There is no objection to the Bassini operation provided that the cord is long enough and is mobile; in fact, it is probably the best operation to use. When there is a long sac or the prolongation of the peritoneum is probably the main part of the operation and all that is necessary afterward is to approximate the conjoint tendon to Poupart's ligament save for the bottom of the canal and without transplantation of the cord. This operation is often serviceable.

CURARE FOR SPASTIC DISORDERS

To the Editor:—May I please have information concerning the use of curare in the treatment of spastic paralysis resulting from a birth injury.

Nicholas Palma, M.D., Paterson, N. J.

ANSWER.—In many cases of spasticity, paralysis agitans or athetosis the intravenous injection of proper preparations of curare is followed by diminution in the hypertonia or involuntary movements at a stage when voluntary motility and respiration are little or not at all embarrassed. The favorable effect may last several days. Suitable standardized preparations are, however, difficult to obtain and the margin of safety is small. The treatment must be regarded as still in an experimental stage and should not be attempted outside of special clinics.

Burman, M. S.: *The Therapeutic Use of Curare and Erythroidine Hydrochloride for Spastic and Dystonic States*, *Arch. Neurol. & Psychiat.* 41: 307 (Feb.) 1939.

SODIUM IODIDE FOR ARTHRITIS

To the Editor:—Will you please give me the rationale of intravenous sodium iodide for arthritis, especially old gonorrheal arthritis. I would like to know the amount given and how often it can be repeated.

M.D., Iowa.

ANSWER.—The use of intravenous sodium iodide in the treatment of arthritis, especially chronic gonorrheal arthritis, is purely empirical. Any improvement noted during the time that such therapy is being administered may be coincidental rather than cause and effect.

BRUCELLA ABORTUS AGGLUTININS AND IMMUNITY

To the Editor:—For how long a time is it possible to obtain a positive agglutination test for *Brucella abortus* in undulant fever after all symptoms have subsided and the patient has apparently recovered? Is it advisable to continue treatment until the test is negative, regardless of symptoms?

M.D., Wisconsin.

ANSWER.—*Brucella abortus* agglutinins may persist for many months or years following recovery from brucellosis (undulant fever). In the majority of instances the agglutinin titer exhibits a declining trend during the first few months following the initial illness. The agglutinins may then disappear or persist at a relatively low level for long periods. In other instances the agglutinin titer may persist at high levels for many months, following the disappearance of all symptoms of brucellosis. The agglutination test does not provide a reliable guide to the immunity status of the patient. Consequently it is inadvisable to regard the agglutination test as a measure of therapeutic effectiveness.

SULFANILAMIDE AND ARSPHENAMINE

To the Editor:—Given a case of gonorrhea and syphilis, is the use of nearsphenamine a contraindication to the simultaneous use of sulfanilamide, neoprontosil and the like for the treatment of gonorrhea?

Robert R. Livingston, M.D., Glenwood Springs, Colo.

ANSWER.—If a patient is suffering from both gonorrhea and syphilis, there is no reason why arspenamine or nearsphenamine and sulfanilamide should not be used concurrently. At the present time there is no available evidence to indicate that the concurrent use of these drugs increases the toxic results which might arise from the individual use of either drug.

VOICE CHANGES FROM INHALATION OF HELIUM-OXYGEN

To the Editor:—What is the explanation for the change in the voice after the inhalation of a few breaths of a helium-oxygen mixture?

M.D., Illinois.

ANSWER.—Human beings are accustomed to talk in an atmosphere of air. Ordinarily the esophagus, larynx and oral passages are filled with air. The velocity of sound in any gas is the function of the density of the molecules. For example, if the temperature and pressure remain the same, the velocity of sound in the air is approximately 330 meters a second and the velocity of sound in helium is 970 meters a second. The velocity of sound in a helium-oxygen mixture (approximately 80 per cent helium and 20 per cent oxygen) is much greater than that in air. Therefore, a person talking in an atmosphere of helium-oxygen mixture would unconsciously set the muscles of his

larynx to cause a sound he expects to hear in air. The fundamental pitch is unaffected but the sound pattern of the resonating cavities of the nasopharyngeal passages is changed. Thus the overtone content is lowered automatically by the mixture and the voice will sound deeper.

INGESTED IODIDE AND HAIR COLOR

To the Editor:—A beautician claims that the hair will appear to change color to reddish brown when the system is saturated with iodine taken even in therapeutic doses. Is this true? He claims that this is thought to be a way of averting gray hair.

P. W. Van Metre, M.D., Rockwell City, Ia.

ANSWER.—If this theory were correct, the world would be full of reddish brown hair, for every syphilitic patient under proper treatment ingests iodine in considerable amounts over long periods. There is no scientific ground for the idea.

CUCUMBERS AND MELONS DURING PREGNANCY

To the Editor:—Is there any basis for the idea that cucumbers and melons of all kinds are contraindicated in a normal pregnancy, i.e. when there is no digestive disturbance? I have been told that they contain histamine, which would have a tendency to produce an abortion.

M.D., Pennsylvania.

ANSWER.—There is no basis for the idea that cucumbers and melons are contraindicated in normal pregnancy. The amount of histamine that these fruits contain is negligible. Even large doses of histamine have little oxytocic action.

EFFECT OF LIVER AND IRON ON LEUKOCYTES

To the Editor:—What is the effect on the differential white count of prolonged liver and iron therapy in secondary anemia?

M.D., Wisconsin.

ANSWER.—Prolonged treatment of secondary anemia with liver and iron has no definite effect on the differential white count. If the liver is given by mouth an eosinophilia frequently results. Liver parenterally may affect the differential in a temporary manner if there is much local reaction or if the patient becomes sensitive to it.

NONINFLAMMABLE X-RAY FILMS

To the Editor:—Will you kindly advise me in what year the present type of noninflammable x-ray film came into general use by the medical profession?

M.D., New Jersey.

ANSWER.—The safety x-ray film was first made available about 1924. It gained rapidly in use after 1928 but was not generally accepted until 1933, when the price was made the same as the nitrate base film.

UNEQUAL BODY DEVELOPMENT

To the Editor:—In *Queries and Minor Notes* in The Journal, June 10, 1934, answer given under the heading "Unequal Body Development" is incomplete. The questioner seeks information regarding the etiology and treatment of persons who are either (1) well developed from the hips downward but of poor development above the hips or (2) normally developed down to the hips but with excessively enlarged legs. The reply states that these may be physiologic variations from the normal and thus overlooks completely the fact that the questioner might be dealing with cases of progressive lipodystrophy, as far as the first type of patient is concerned, and with Milroy's disease as regards the second type.

A. M. Targow, M.D., Chicago.

COCYGYDYNIA

To the Editor:—In *Queries and Minor Notes* in The Journal, June 17, 1934, 2553, appears a discussion of the treatment of coccygodynia. Accord- to recent literature on this syndrome, pain is present about the coccyx and superior gluteal region and even along the course of the sciatic nerve. Examination usually reveals muscle spasm of the levator ani and the piriformis and coccygeus muscles. In order to obtain relief, treatment must be directed to produce an amelioration of muscle spasm by heat and massage. The discussion fails to make any mention of this most important therapeutic measure of massage. Treatment is carried out as follows: Pelvic muscular relaxation is begun by placing the patient in a hot bath, whirlpool, or by the use of pelvic diathermy. The index finger is inserted full length into the rectum and pressure is directed posterolaterally, with stroking in the direction of the long axis of the muscle fibers. Massage is gentle at first so as not to traumatize the tender muscles, but in subsequent visits the pressure of massage is increased. Failure to obtain some measure of relief in from six to eight treatments calls for the consultation of an orthopedist. Thiele (The Journal, Oct. 16, 1933, p. 1271) and eight associated practitioners treated eighty patients by this method and noted cures in 60 per cent, improvement in 33 per cent and failure in 6.3 per cent.

M. K. Newman, M.D., and J. M. Berris, M.D., Detroit.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, August 12, page 619.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Basic Science. Tucson, Sept. 19. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

ARKANSAS: Medical (Regular). Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. Medical (Eclectic). Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Written examination. Sacramento, Oct. 16-19. Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Endorsement. Denver, Oct. 3. Examination. Denver, Oct. 4-6. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: Basic Science. New Haven, Oct. 14. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven. Medical (Regular). Examination. Hartford, Nov. 14-15. Endorsement. Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Medical (Homeopathic). Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DISTRICT OF COLUMBIA: Basic Science. Washington, Oct. 23-24. Medical. Washington, Nov. 13-14. Formal application and supporting data must be received before Oct. 1. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 10-11. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

IDAHO: Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Whittlesley, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 17-19. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: Basic Science. Des Moines, Oct. 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Regular. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Lansing, Oct. 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: Basic Science. Minneapolis, Oct. 3-4. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical. Minneapolis, Oct. 17-19. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Reciprocity. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Reciprocity. Helena, Oct. 2. Examination. Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: Basic Science. Lincoln, Oct. 3-4. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, Oct. 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 18-21. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: Basic Science. Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PUERTO RICO: Santurce, Sept. 5. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, Oct. 5-6. Sec., Board of Examiners in Medicine, Dr. Robert M. Lord, 122 Waterman Ave., Providence.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WISCONSIN: Basic Science. Madison, Sept. 23. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. Medical. Madison, Jan. 9-11. Sec., Dr. Henry J. Gramling, 507 Mariner Tower, Milwaukee.

WYOMING: Cheyenne, October. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

South Carolina June Examination

Dr. A. Earle Boozer, secretary, State Board of Medical Examiners of South Carolina, reports the written examination held at Columbia, June 26-28, 1939. The examination covered seventeen subjects and included forty-eight questions. An average of 75 per cent was required to pass. Forty-five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Howard University College of Medicine.....	(1937)		76.4
Indiana University School of Medicine.....			86.4
Tulane University of Louisiana.....			87
Temple University School of Medicine.....			80.9
University of Pennsylvania School of Medicine.....			75.1
Medical College of the State.....	78.3, 78.3, 78.4, 78.6, 79, 79.5, 80, 80.4, 80.9, 81.6, 81.8, 81.9, 82.4, 82.6, 82.8, 83, 83.1, 83.3, 83.5, 83.5, 84.3, 84.5, 85, 85.1, 85.5, 85.8, 86.1, 86.1, 86.3, 86.5, 88.5, 88.8, 89.4, 89.5, 90.9, 90.9		
University of Tennessee College of Medicine.....	(1937)		82.5
Vanderbilt University School of Medicine.....	(1935) 78.5, (1939)		85

Seven physicians were licensed by reciprocity on April 12 and July 11. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Georgia Medical Department.....	(1929)		Georgia
University of Louisville School of Medicine.....	(1937)		Kentucky
Johns Hopkins University School of Medicine.....	(1929)		Ohio
University of Minnesota Medical School.....	(1929)		N. Carolina
Meharry Medical College.....	(1920)		Georgia
(1937) Tennessee			
University of Tennessee College of Medicine.....	(1929)		Alabama

Kansas June Report

Dr. J. F. Hassig, secretary, Kansas State Board of Medical Registration and Examination, reports the written examination held at Kansas City, June 13-14, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Seventy-eight candidates were examined, all of whom passed. Eight physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....	(1937)		87.4
School of Medicine of the Division of the Biological Sciences.....	(1938)		81.7
University of Kansas School of Medicine.....	(1939)		76.9,
77.4, 80.7, 80.8, 81.2, 81.3, 81.3, 81.6, 81.6, 82.4, 82.5, 82.6, 82.6, 82.8, 82.9, 83.1, 83.1, 83.2, 83.3, 83.7, 83.9, 83.9, 84.1, 84.2, 84.3, 84.4, 84.5, 84.5, 84.5, 84.6, 84.9, 85, 85.1, 85.2, 85.5, 85.7, 86.3, 86.4, 86.5, 86.6, 86.6, 86.8, 86.9, 87, 87.1, 87.1, 87.3, 87.5, 87.5, 87.6, 87.6, 87.7, 87.7, 87.7, 87.8, 87.9, 88.1, 88.7, 88.8, 89.7, 89.7, 89.9, 90, 91.1, 91.2, 91.4, 91.8			
University of Michigan Medical School.....	(1937)		85.8
School of Medicine.....	(1939)		88.6
School of Medicine.....	(1938)		83.7,
College of Medicine.....	(1938)		84.5
Medical School.....	(1938)		87, 87.1

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Indiana University School of Medicine.....	(1929)		Indiana
Tulane University of Louisiana School of Medicine.....	(1938)		Louisiana
Harvard Medical School.....	(1933)		Penna.
University of Michigan Medical School.....	(1937)		Michigan
Washington University School of Medicine.....			Missouri
University of Oklahoma School of Medicine.....			Oklahoma
Baylor University College of Medicine.....			Texas

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Cornell University Medical College.....	(1929)		N. B. M. Ex.

Oregon June Examination

Dr. Joseph F. Wood, secretary, Oregon State Board of Medical Examiners, reports the written examination held at Portland, June 20-22, 1939. The examination covered sixteen subjects. An average of 75 per cent was required to pass. Seventeen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Stanford University School of Medicine.....	(1938)		87.3
Northwestern University Medical School.....	(1938)		82*
Rush Medical College.....	(1938)		85.9
University of Louisville School of Medicine.....	(1934)		87.1

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
Harvard Medical School.....	(1936)	N. B. M. Ex.

* This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.

† Licensed to practice osteopathy and surgery.

Book Notices

Community Health Organization: A Manual of Administration and Procedure Primarily for Urban Areas. Edited by Ira V. Hiscock, Professor of Public Health, Yale University School of Medicine, New Haven, Connecticut. Third edition. Cloth. Price, \$2.50. Pp. 318. New York: Commonwealth Fund; London: Oxford University Press, 1939.

This well known book gives the most complete and comprehensive, as well as detailed, description of how a community can organize itself for health. It deals with official agencies, voluntary agencies, hospitals and outpatient facilities, the financial aspects of health in the community, health surveys, school health services and the newer health problems, such as nutrition, mental hygiene, industrial hygiene, cancer and heart disease. To the medical reader the book is disappointing in that it gives less attention to the part played by organized medicine in community health organization and in that it does not acknowledge the fact that many of the health surveys and so-called health studies which have been made in recent years have been challenged as to their validity by the medical profession. Each chapter includes a table of salaries and other budgetary items, which in most instances are considerably in excess of sums which most cities or even states have shown a willingness to provide up to the present. The book is of special usefulness to the public health worker and the student of public health. It should be interesting and valuable also to physicians serving organized medicine on public health and public relation committees, to give them an understanding of the existing organization of public health departments and the recommendations of those who have studied methods and organization in the public health field in many communities. The editor of the book, though not a physician, has been notably open minded in giving due place to the physician in the health picture. In this book more stress is laid on the physician attached to health departments, schools and other organized agencies than to the practicing physician, who should be drawn more and more into the public health program, as recognized on page 226, in connection with cancer, where the statement is made "The family physician is the key person in the cancer control movement; on his judgment the final result often depends." The family physician is also the key person in practically all public health movements, and on his judgment depends the final outcome.

Practical Child Psychotherapy. By Dr. Curt Boenheim. With a foreword by Prof. Dr. H. Finkelstein. Cloth. Price, 10s. 6d. Pp. 177. London: John Bale Medical Publications, Ltd., 1938.

The author has provided a short, comprehensive book on practical child psychotherapy presented from a medical point of view. Only those conditions which are most important from the standpoint of the pediatrician and general practitioner are discussed. The author has an intimate knowledge of children and their normal reactions and has used this knowledge to temper and to mold his attitudes as to the appropriate psychotherapeutic methods to be applied in a given case. Throughout the entire presentation the common sense approach is apparent.

The book has two main divisions. In the first there is a brief discussion of the concepts embodied in the various schools of psychology. It is apparent that the author subscribes at

least in part to the teachings of the psychoanalytic school. However, when considering the indications for analytic treatment he sharply differentiates the more or less transient abnormalities occurring in children (the type being largely dependent on the stage of development of the child) and the deep rooted, more or less permanent maladjustments occurring in adults. He also presents the indications for psychotherapy and the methods of choice in individual cases. He states that therapeutic methods should be chosen in accordance with the type and severity of the disorder, ranging from simple reassurance of the parents to psychoanalytic methods for the more difficult problems. In contradistinction to the analytic school, which opposes the treatment of symptoms themselves, fearing that this may merely lead to a covering of a personality difficulty, the author believes that in childhood the symptoms need not reflect some deep rooted disorder. Therefore successful therapy directed at the symptom may clear up the entire situation. Any method, whether medical or psychotherapeutic, that can alter the situation is acceptable.

The second portion of the book deals with the various disorders and the appropriate therapy in each case. The discussion of enuresis, sleep disorders and motor disturbances (tics, non-epileptic fits) is especially good. The author definitely feels that a majority of the so-called behavior disturbances of children can be treated by the pediatrician and general practitioner. He is a pediatrician who has specialized in child psychology and psychotherapy, and hence his book reflects tried and true pediatric principles coupled with the specialized techniques of modern psychotherapy.

The Chicago Recreation Survey 1937. Volume III: Private Recreation. A Project Sponsored Jointly by the Chicago Recreation Commission and Northwestern University. By Arthur J. Todd, Chairman, Department of Sociology, Northwestern University. In collaboration with William F. Byron, Chairman, Division of Social Work, Northwestern University, Howard L. Vierow, Director, Chicago Recreation Survey. Conducted under the auspices of the Works Progress Administration, National Youth Administration and Illinois Emergency Relief Commission. Paper. Pp. 167, with illustrations. Chicago, 1938.

This is volume III of the Chicago Recreation Survey, of which previous volumes have been reviewed in *THE JOURNAL* (Sept. 3, 1938, p. 965). The current volume deals with private recreational opportunities as distinguished from public recreational facilities and commercial recreational enterprises. It takes in therefore settlements, community centers and related group work agencies, boys' clubs, the Y. M. C. A., the C. Y. O., the K. of C., B'nai B'rith, Boy Scouts, Girl Scouts, Campfire Girls, Girl Reserves, nationality groups, fraternal organizations, social clubs, athletic organizations, private contributions to art, music, literature and drama, industrial and trade union recreation, and miscellaneous topics such as hobby and special interest clubs, housing projects and district recreation committees. Each of these topics receives attention in a narrative chapter in which are given the essential facts about establishment, organization, membership, purposes and budgets. Like the companion volumes in the series, this study is well illustrated with colored maps showing population and the distribution of various recreational facilities, such as the Chicago Federation of Settlements, miscellaneous settlement houses and neighborhood centers, religious agencies, gymnasiums, boys' clubs, the Y. M. C. A., the Y. W. C. A., the C. Y. O., K. of C. Councils, Boy Scouts, Girl Reserves, Girl Scouts, Campfire Girls, foreign language groups, Masonic lodges, luncheon service clubs, American Legion posts and auxiliaries, private golf clubs, softball playing fields and camps, the distribution of juvenile delinquents and the relationship of delinquents to boy population between the ages of 10 and 16. The study is a storehouse of information. The conclusions are left largely to the reader, and there is no formal chapter on conclusions and recommendations. To a great extent the facts are permitted to tell the story, which is perhaps best summarized in a quotation from page 5: "Private philanthropy is perhaps more necessary than ever to preserve alive the humane spirit against the inroads of routine and professionalism; and to find new paths through experimentation. Much the same may be said of private agencies doing work of the handicapped . . . the private agencies are indispensable to all fields of social amelioration. They never were more needful in the field of recreation than at the present moment."

Dental Surgery and Pathology. By J. F. Colyer, K.B.E., LL.D., F.R.C.S., Consulting Dental Surgeon to Charing Cross Hospital, London, and Evelyn Sprawson, M.D., D.Sc., M.R.C.S., Dental Surgeon and Lecturer on Dental Surgery and Pathology to the London Hospital. Seventh edition. Cloth. Price, \$12. Pp. 1,067, with 979 illustrations. New York, Toronto & London: Longmans, Green & Co., 1938.

This volume will be of greater interest to the practicing dentist who does minor surgical interventions than to the surgeon who is practicing major surgical operations and is particularly interested in diseases and conditions of the mouth and face. The first half deals comprehensively with dental problems, such as pathologic dentition, variations in the size, structure and position of the teeth, abnormalities of position and occlusion. In chapters x and xi the authors discuss caries, while in chapter xiii they consider diseases of the pulp. Chapter xxvii will be of especial interest to the dentist, as it is devoted to dental radiology, including the technic of dealing with and the diagnosis of pathologic conditions. Chapter xxviii considers the extraction and surgical removal of teeth. Chapter xxxv is especially helpful to the dentist, as it treats of rather unusual conditions encountered in the course of dental practice, such as burning of the tongue and mouth in blood dyscrasias. The book is well written and should appeal to the dentist who is interested more in disease conditions of the oral cavity than in simple dental repair.

Problems of Ageing: Biological and Medical Aspects. Edited by E. V. Cowdry. A Publication of the Josiah Macy Jr. Foundation. Cloth. Price, \$10. Pp. 758, with 121 illustrations. Baltimore: Williams & Wilkins Company, 1939.

This book consists of articles by a number of competent scientists on major special problems of aging. The list of the authors and chapter headings will give a good general idea of the authorship and the scope of the book: William Crocker, aging in plants; H. S. Jennings, senescence and death in protozoa and invertebrates; L. O. Howard, aging of insects; T. Wingate Todd, aging of vertebrates; Clark Wissler, human cultural levels; Louis I. Dublin, longevity in retrospect and in prospect; A. E. Cohn, cardiovascular system and blood; E. B. Krumbhaar, lymphatic tissue; A. C. Ivy, digestive system; Jean R. Oliver, urinary system; T. Wingate Todd, skeleton, locomotor system and teeth; F. D. Weidman, aging of the skin; A. J. Carlson, the thyroid, pancreatic islets, parathyroids, adrenals, thymus and pituitary; Edgar Allen, female reproductive system; Earl T. Engle, male reproductive system; G. V. Hamilton, changes in personality and psychosexual phenomena with age; Macdonald Critchley, aging of the nervous system; Jonas S. Friedenwald, the eye; Stacy R. Guild, the ear; Walter R. Miles, psychological aspects of aging; C. M. McCay, chemical aspects of aging; Walter B. Cannon, aging of homeostatic mechanisms; E. V. Cowdry, aging of tissue fluids; William deB. MacNider, aging processes considered in relation to tissue susceptibility and resistance, and Lewellys F. Barker, aging from the point of view of the clinician. It is an important and timely contribution, in fact the most comprehensive and authoritative volume on aging now available.

Interns Handbook: A Guide, Especially in Emergencies, for the Intern and the Physician in General Practice. By Members of the Faculty of the College of Medicine, Syracuse University, Syracuse, N. Y. Under the direction of M. S. Dooley, A.B., M.D., Chairman Publication Committee. Second edition. Cloth. Price, \$3. Pp. 523, with 10 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1938.

This volume contains much information that should be useful to the intern. An attempt is made, however, to cover entirely too much territory for a handbook. The book was devised by an editorial committee aided by thirty-five other committees (each with from one to thirteen members), consisting of committees on allergy, anesthesia, antisyphilitic treatment, dehydration, dermatology, diet drugs, fever, gynecology, injuries of the head, history, infectious diseases, intern relations, laboratory, medical jurisprudence, medicine, neurology, nursing, obstetrics, ophthalmology, otolaryngology, pediatrics, proctology, psychiatry, resuscitation, serums and vaccines, sex hormones, shock, social service, solutions, surgery, toxicology, urology, vehicles and flavors, and vitamins. The first section deals with the relation of the intern, hospital and public and contains a section on medical jurisprudence which has some material that is not

applicable in all states. The section on laboratory medicine comprises useful information on bacteriologic, biochemical and pathologic tests. The general section on medicine and surgery attempts to cover the hospital treatment features of many diseases. The statement which appears under the heading "Lobar Pneumonia"—"The complete treatment of lobar pneumonia is beyond the scope of this book"—might well be applied to many of the other discussions in this volume. It is granted the author that some of these sections are followed by bibliographies, but it seems unlikely that the average graduate of the modern medical school would be unfamiliar with an adequate bibliography for the treatment of conditions which he encounters in the hospital. Furthermore, the availability in the average hospital of the *Quarterly Cumulative Index Medicus* would give him the latest references to these subjects. The monographs on drugs are well prepared, but they are listed under their Latin names, so that in some instances to locate them may be time consuming to the intern. It is surprising that the author finds it essential to give an outline of a history and physical examination, as it would seem reasonable to presume that the training of class A medical schools should have made the intern adept at including all essential information in taking histories and reporting physical examinations. The advisability of including such brief information as the following may be questioned:

Carcinoma of the Skin:

Epitheliomas, the most important of which are (a) squamous or prickle-cell; (b) basal cell. They are usually not serious if an early diagnosis and removal is made. The history of a preexisting growth such as a keratosis suddenly enlarging suggests malignant change.

Treatment. Complete destruction by radium, roentgen ray, electrocoagulation or surgical excision. Do a biopsy at the time of removal to confirm the diagnosis and to guide further treatment.

The volume is a useful one for those who keep in mind the fact that for adequate information on some of the subjects discussed bibliographies given in the handbook and other references are necessary.

El volumen de la sangre circulante y sus variaciones normales y patológicas: Estudio clínico-experimental. Por el Dr. Elias Levin, Jefe de Clínica del Hospital Rosario. Con prefacio del Profesor Bernardo A. Houssay. Paper. Pp. 294, with 25 illustrations. Rosario: Establ. Graf. Pomponio, 1938.

The introduction deals adequately with the distinction between circulating blood volume and the total volume of blood in the body, of which a part is usually in an organ of blood storage, as the spleen, skin, liver, great veins or lungs. The author describes in detail the method he uses, injecting trypan-red and sampling the blood twice at three-four and five-seven minutes. He uses a colorimeter to determine the extent of dilution of the dye in plasma. In a series of fifty-six normal persons from 19 to 73 years of age the average blood volume was 78 cc. per kilogram of body weight, of which plasma made up 42 cc. per kilogram and cells 36 cc. per kilogram. Acceptable variation in duplicate determinations was 4 per cent or less. In the chapter on physiologic variations in volume he emphasizes the increase in circulating blood volume on exposure to heat but presents no data of his own on that. There was a consistent fall when a subject is studied seated upright to a figure about 7 per cent less than when lying down. In four unstable emotional subjects this fall was much more marked, averaging a 17 per cent diminution in circulating blood volume. The author has made many determinations at short time intervals to ascertain what effect on blood volume acute experiments have, and he includes data on the effect of drinking water, of alcohol, of thyroxine and of muscular work in healthy and sick subjects. Of interest is the splenectomized subject, who showed a 5 per cent diminution in circulating blood volume on exertion. About 1,000 determinations were done, mostly on sick subjects, and some data are presented on hemorrhage shock, anesthesia, fevers, polycythemia and blood dyscrasias and kidney diseases, which in general agree with the present concepts. The largest single group of data refers to cardiac patients and consists of a table listing the state of circulation with the blood volume in fifty-three such cases. It is quite obvious that decompensation is regularly associated with a significant increase in the circulating blood volume. There is a good index and bibliography, including titles. The author believes that, if a sufficiently simple technic could be perfected, blood volume measurements would be routine in hospital prac-

tice. However, he has used his method as a research tool and presents his data to clinicians for them to know about in studying their cases. He has helped especially in the serial measurements on the same subject.

Educating for Health: A Study of Programs for Adults. By Frank Ernest Hill. Boards. Price, \$1.25. Pp. 224. New York: American Association for Adult Education, 1939.

This book deals, as its title indicates, with health education programs for adults. The author starts out with a brief review of health education down through the ages, finding little prior to Chadwick and Shattuck in the nineteenth century. Approaching the modern picture he gives a general outline of educational influences in the community and then proceeds to discuss specific organizations engaged in health education, including the American Public Health Association, the American Medical Association, the National Organization for Public Health Nursing and the voluntary health agencies in such fields as of tuberculosis and mental hygiene. Attention is given to the Red Cross, the Maternity Center Association of New York, the New York Academy of Medicine and other community groups. Much attention is devoted to health centers, as exemplified in the health districts of Greater New York, and to health departments as educators. The book is an excellent and comprehensive survey of the health education situation in the United States today. It is obviously intended as an objective and frankly critical book. To none of the organizations mentioned does the author give unmixing praise. He attempts to see weaknesses as well as merits in the programs of health education put forward by doctors through the American Medical Association, public health workers through the American Public Health Association, nurses through the National Organization for Public Health Nursing, and other groups through their respective special organizations. The medical reader will not agree with all the author's criticisms of the American Medical Association, but he will be compelled to recognize that the author, even when mistaken, has obviously made an effort to present his honest opinion. That this is not more favorable to organized medicine may be due to the fact that he has accepted, as have many other writers, statements from sources which were formerly authentic but from which in recent years have emanated some so-called studies of doubtful authenticity.

Carbon Monoxide Asphyxia. By Cecil K. Drinker, M.D., D.Sc., Professor of Physiology and Dean, School of Public Health, Harvard University, Boston. Cloth. Price, \$4.50. Pp. 276, with 40 illustrations. New York, Toronto & London: Oxford University Press, 1938.

The hazard of carbon monoxide asphyxia is considerable in many important industries. Some 40,000 people die each year of this and related causes. During the past few years there have been extensive studies on the subject, and the bibliography included in this volume lists hundreds of references. After considering the physiology and biochemistry of carbon monoxide asphyxia, the author takes up acute poisoning and the problem of the after-effects, next the determination of what constitutes harmful exposure and then the statistics, the pathology and the treatment. Final chapters are concerned with technical methods dealing with the detection and determination of carbon monoxide in the air and in the body. There are an extensive bibliography and both author and subject indexes as well as forty illustrations and twenty-one tables supplying important information and data. The chapter on analytic methods was prepared by Dr. Julius Sendroy Jr. Certainly it is the most reliable and concentrated work on the subject thus far available.

Industrial Hygiene: A Handbook of Hygiene and Toxicology for Engineers and Plant Managers. By Laurence B. Chenoweth, A.B., M.D., and Willard Machle, B.S., M.D. With a foreword by Herman Schneider, Sc.D., LL.D. Cloth. Price, \$2. Pp. 235, with 104 illustrations. New York: F. S. Crofts & Co., 1938.

This volume has been particularly designed to acquaint engineers and plant managers with the advantages accruing to employer and employee alike of a planned approach to injury and disease control in industry. As such it emphasizes primarily the importance of prevention and early emergency treatment. The authors have succeeded well enough to merit a wider audience, for in spite of its limitations in scope this book could be read with profit by the practitioner who needs an introduction to industrial problems which he meets only occasionally.

Cáncer laringeo: Su tratamiento quirúrgico. Por el Dr. Ricardo E. Bisi, médico del Servicio de oto-rino-laringología de los Hospitales Nacionales de Clínicas y Alvear. Paper. Pp. 355, with 101 illustrations. Buenos Aires: Librería y Editorial "El Ateneo," 1938.

This is one of the most important books published on the subject of malignant disease. It derives particular importance from two clinical facts, namely that cancer of the larynx is on the increase and that it is a curable disease if diagnosed early. In conformity with the latest thought on the subject the importance of roentgenologic studies in the delineation of cancer of the larynx is emphasized. Excellent lateral roentgenograms and schematic interpretations of Malenchini, Carminati and Leroux-Robert are well presented. Frontal tomographs by the technic of Felix Leborgne illustrate the importance of this method of x-ray study of the larynx. Irradiation as a means of treatment is not considered; as stated in the title, the book is concerned only with surgical treatment. The author does not regard histologic grading as of any importance in planning treatment. Recurrence he has found to depend on the possibility of complete operative extirpation according to location and stage rather than on degrees of malignant involvement as shown by histologic type. The surgical technic is based on the large clinical experience of the author and of his father, Dr. Humberto Bisi, to whom the book is dedicated. Preliminary tracheotomy is avoided whenever possible. Anesthesia by local and regional means is preferred. The steps of all surgical procedures are clearly given in detail. The author favors and gives the technic of the most radical extirpations of cancer of the larynx, pharynx, tongue, cervical esophagus and the lymphatic metastases. If necessary to get all of the latter the anterior cervical muscles, including the sternomastoids, are extirpated. The book is invaluable to all surgeons who are called on to deal with cancer of the larynx.

Soviet Samples: Diary of an American Physiologist. By Percy M. Dawson, M.D. Paper. Price, \$4.25. Pp. 568. Ann Arbor, Michigan: Edwards Brothers, Inc., 1938.

This book is printed by the lithoprint technic, which copies the typewritten page. It represents the diary of the author and a number of his theories of publication, including simplified spelling and abbreviations. These do not add to the ease of perusal. For those who will take the necessary time to read this work, and it is hard to take in large doses, there is a great deal of information about conditions in Russia. There is also a vast amount of irrelevant and unnecessary information, which serves little useful purpose. Occasionally the simplified spelling gives an Artemus Ward impression. For example the sentence

I enquired if in putting up tomatoes their vitamins ar' conserved & was told that they ar

and also the paragraph

Throught the inspection the doctor wd. say "Now this is a brite & airy room" & make similar comments, & when we returned to her office, she sat by an open window where the wind waved her hair and fluttered the papers on her desk. She believes that it wil not be long before there is a universal demand for good ventilation.

A Treatise on the Surgical Technique of Otorhinolaryngology. By Georges Portmann, Professor of Otorhinolaryngology at the Medical School of the University of Bordeaux. Collaborators: H. Retrouffy, J. Despons, P. Leduc and G. Martinaud, Attending Clinicians of the Otorhinolaryngology Department of the School of Medicine of the University of Bordeaux. Translation by Pierre Viole, M.D., Associate Clinical Professor of Surgery in the Department of Otorhinolaryngology of the University of Southern California School of Medicine, Los Angeles. Cloth. Price, \$12.50. Pp. 675, with 476 illustrations. Baltimore: William Wood & Company, 1939.

The author is well known in this country; he has been the guest of learned societies here and is highly respected as one of the leaders in his field on the continent. This work represents his personal experience with operative surgery. Under the circumstances, it is not strange that some of the interventions practiced by him are not the vogue in this country and that some of the procedures used here are not dwelt on. Nevertheless the volume has great value, because it represents the experience of a seasoned operator. What he has set out to do has been done exceedingly well. Each operation is discussed from beginning to end, by way of text, photographs and draw-

ings. Preoperative and postoperative measures are considered as well. The author has no intent to teach technic by way of a book, but the printed page here does give in a superlative manner an insight into the principles of operative surgery of the ear, nose and throat as practiced by an accomplished exponent.

Röntgenatlas der Erkrankungen des Herzens und der Gefäße: Ein Leitfaden für Ärzte. Von Dr. Walter Brednow, a. o. Professor für Innere Medizin und Röntgenologie, Oberarzt der Medizinischen Universitäts-Klinik Göttingen. Second edition. Paper. Pp. 161, with 90 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1939.

The second edition is not essentially different in general plan from the first. New illustrations enrich the beautiful collection of cardiovascular roentgenograms, which are often clarified by photographs of plaster models. Roentgenkymography of the heart is described, but it is the opinion of the author that this new technical advance, while promising real help in cardiac diagnosis when it is fully developed, has not yet achieved a place in the armamentarium of the practicing physician. The roentgenograms are clearly reproduced and should be of great value to students and teachers of cardiography.

The History of Bacteriology. By William Bulloch, M.D., F.R.S. University of London, Heath Clark Lectures, 1936, delivered at the London School of Hygiene and Tropical Medicine. Cloth. Price, \$3.75. Pp. 422, with 52 illustrations, including 16 plates. New York, Toronto & London: Oxford University Press, 1938.

This volume includes the Heath Clark lectures delivered at the London School of Hygiene and Tropical Medicine in 1936. Its author prepared "The History of Bacteriology," which appeared in "The System of Bacteriology" published some years ago by the Medical Research Council of Great Britain. In taking up the subject the author considers first ancient doctrines of the nature of contagion; then follows the evolutionary development of our knowledge of bacteriology to the period of classification of bacteria and the history of doctrines of immunity. There are also a bibliography and some excellent biographic notes concerning early workers in the field of bacteriology. These are quoted from a variety of literary sources throughout the world. The book is beautifully printed, handsomely illustrated and indispensable to all who are concerned with the history of the science that it covers.

The Chemistry of Natural Immunity. By William Frederick Koch, Ph.D., M.D. Cloth. Price, \$2. Pp. 199, with illustrations. Boston: Christopher Publishing House, 1938.

The author of this book for years has promoted a remedy for the treatment of cancer which has been a not infrequent subject of adverse reports in *THE JOURNAL*. The first portion of the book is an attempt to formulate a biochemical explanation of observations made by various scientific workers in the field of physiology and pathology. The second portion contains brief histories of cases in which cancer and many other conditions, according to the author, have been amenable to "Glyoxylide." If Dr. Koch were successful in treating cancer (which had been established as such beyond all doubt by repeated diagnoses), his clinic by this time would be overrun by thousands of patients. If Koch's solution is truly the chemical he describes, it is obviously so unstable that it would probably not be the same substance when it reached far distant points and the container was opened for injection. Case histories without adequate explanation of when and where or by whom the condition was diagnosed, and where and when and by whom a cure was pronounced, lack the essential elements of scientific evidence.

Clinical Studies in Psychopathology: A Contribution to the Aetiology of Neuritic Illness. By Henry V. Dicks, M.A., M.D., M.R.C.P., Assistant Medical Director, The Tavistock Clinic, London. Cloth. Price, \$4.75. Pp. 248. Baltimore: William Wood & Company, 1939.

This volume includes a series of postgraduate lectures at the Tavistock Clinic. It does not provide any originality but instead attempts to reflect the author's opinions and views of various psychoanalytic concepts. The author has borrowed freely from Freud, Jung and Adler. Presenting a limited number of cases, he discusses the anxiety states, neurasthenia, obsessional states, hysteria and various sexual abnormalities, concluding with drug addiction. The author inclines toward the idea that the future of psychiatry will be determined by the trend toward psychosomatic considerations.

The Nobel Prizes and Their Founder Alfred Nobel. By Fritz Henriksson. Paper. Price, \$1. Pp. 59, with 9 illustrations. Stockholm: Alb. Bonniers Boktryckeri, 1938.

This pamphlet makes available all the necessary factual data concerning the Nobel prizes, the manner in which they were established and the method of award and a complete list of those who had received the prizes up to the date of publication. There are also some thirty pages of information relative to Alfred Nobel and his family. It is the authentic publication for those wishing information in this field.

It's More Fun to Be Thin. By Jean Z. Owen. Cloth. Price, \$2. Pp. 182, with illustrations. Boston: Marshall Jones Company, 1939.

This book is a badly overdone attempt to sugarcoat education about reducing. It consists mostly of forced humor with a small amount of information. Of 182 pages, only seven are devoted to an actual week's reducing diet, and there are a few scattered menus in other parts of the book. The diet recommended is deficient in protein, deficient in carbohydrate and almost totally lacking in dairy products, with the exception of a small allowance of butter. In the entire collection of sample menus for a week, milk is not advised. Great emphasis is placed on using rye bread instead of white, when the most elementary knowledge of caloric values should have taught the author that rye bread has practically the same caloric value as white. In the presence of many better books and pamphlets, this one can hardly be recommended.

Bacteria: The Smallest of Living Organisms (1872). By Dr. Ferdinand Cohn. Translated by Charles S. Dolley (1881). Introduction by Morris C. Leikind. Boards. Price, \$1. Pp. 44, with 2 illustrations. Baltimore: Johns Hopkins Press, 1939.

This reprint from the *Bulletin of the History of Medicine* makes available one of the most important essays in the history of bacteriology. First published in 1872, it appeared when Pasteur was in the midst of his studies on fermentation and spontaneous generation and when Koch was still an unknown physician.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Chiropractic: Scope of Chiropractic in California; "Chiropractic as Taught in Chiropractic Schools" Construed.—The defendant was a chiropractor licensed under the provisions of the chiropractic initiative act adopted in California in 1922. He was convicted of a violation of the medical practice act, now forming a part of the Business and Professions Code of California, and appealed to the appellate department, superior court, Los Angeles County, California.

It was not necessary, the court said, for the complaint to negative the possession of a chiropractic license by the defendant. The operative effect of the 1922 chiropractic initiative was the same as that of an exception or limiting proviso placed in the same act with a prohibition which is not a part of the definition of the offense. It is the rule in such matters that it is not necessary in a criminal charge to negative such an exception or proviso.

Prior to the 1922 chiropractic initiative, chiropractors in California could by virtue of a provision in the medical practice act obtain from the board of medical examiners licenses to practice as drugless practitioners, without the use of drugs or medical preparations and without severing or penetrating any of the tissues of human beings, except the severing of the umbilical cord. The 1922 chiropractic initiative created a board of chiropractic examiners and provided that a license issued by the board authorized the holder—

to practice chiropractic in the State of California as taught in chiropractic schools or colleges; and, also, to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body, but shall not authorize the practice of medicine, surgery, osteopathy, dentistry or optometry, nor the use of any drug or medicine now or hereafter included in materia medica.

The proponents of the 1922 initiative, the court pointed out, then argued that their complaint was not against the limited

form of license under which they practiced but against the unfair administration of the medical practice act as it applied to chiropractors. They assured the voters that the proposed initiative prohibited the use of "drugs, surgery or the practice of obstetrics by chiropractors." This argument, the court said, while not conclusive, may be considered as an aid in interpreting the initiative. The decision of the court in this case does not indicate, except by inference, specifically the type of practice in which the defendant engaged. It does discuss exhaustively the scope of chiropractic in California.

The court disagreed with the defendant's contention that he was authorized to practice any method of healing that is taught in chiropractic schools and colleges. The practice authorized by the initiative, the court observed, must be "chiropractic," and it must also be "as taught in chiropractic colleges." Neither of these expressions can rule the meaning of the initiative to the exclusion of the other. The court quoted from various sources to show that the term "chiropractic," at the time the initiative was adopted in 1922, meant a system of healing that treated disease by manipulation by hand of the spinal column. This general consensus of definitions, the court continued, showed what was meant by the term "chiropractic" when used in the initiative act, for the words of an act must be taken in the sense in which they were understood at the time when the act was enacted. Nor, the court observed, has the accepted definition of the word since changed. The effect of the words "as taught in chiropractic schools or colleges" is not to set at large the signification of "chiropractic," leaving the schools and colleges to fix on it any meaning they choose. The scope of chiropractic being well known, the schools and colleges, so far as the authorization of the chiropractor's license is concerned, must stay within its boundaries. They cannot exceed or enlarge them. The trial court, in the opinion of the appellate court, correctly instructed the jury as follows:

It is thus seen that the authority granted to a chiropractor to practice the arts taught in chiropractic schools and colleges is limited by the restriction that such practice may not invade the field of medicine or surgery, nor may the chiropractor use any drug or medicine included in *materia medica*, even though certain phases of the practice of medicine or surgery or the use of such drugs or medicines may have been taught in chiropractic schools or colleges. In other words, the chiropractor is limited to the practice of chiropractic and the use of mechanical hygienic and sanitary measures incident to the care of the body, which do not invade the field of medicine and surgery, irrespective of whether or not additional phases of the healing art, including medicine and surgery or the use of drugs, may have been taught in chiropractic schools or colleges.

The defendant contended that the limiting language found in the chiropractic initiative act that licenses issued thereunder shall not authorize the practice of medicine, surgery, osteopathy, dentistry or optometry, nor the use of any drug or medicine now or hereafter included in *materia medica*, was purely surplusage and should be wholly disregarded. This was certainly not the position taken by the proponents of the 1922 initiative, the court pointed out, nor did the people have any such intent in adopting the act, if they paid any attention to the positive assurance given them by the proponents, as the court supposed they did. The defendant argued that chiropractic is merely a phase of medicine and surgery, and since the license provided by the initiative act expressly permits the practice of chiropractic, the limitation was repugnant to the grant and must be ignored. But, the court pointed out, all the parts of an act must be considered together and meaning and effect must be given, if possible, to each and every part. The initiative must, then, mean something by its provision that a chiropractic license shall not authorize the practice of medicine or surgery. Obviously, it does not mean to prohibit what has just been expressly authorized; that is, the practice of chiropractic. In view of the fact that the proponents of the initiative declared in 1922 that "the teachings and practice of chiropractic are admittedly different from those of medicine," that there was no objection to the scope of the license which a chiropractor could obtain under the medical practice act and that under the proposed initiative chiropractors could not use drugs or surgery, the court in the present case concluded that the words "medicine" and "surgery" as used in the initiative act were intended to continue as to chiropractors the limitations

imposed on drugless healers by the medical practice act; that is, to deny them the use of drugs and medical preparations and the severing or penetrating of the tissues of human beings.

The defendant objected to an instruction given by the trial court that excluded chiropractors from the use of proprietary medicines. But, the appellate court said, that instruction was in accordance with the language of the initiative itself, which makes no exception of medicines that are "proprietary." The act declares that persons licensed under it shall not practice medicine, a practice which certainly includes the use and prescribing of medicines in whatever form or combination they may be prepared or sold. It also prohibits the use by licensees of "any drug or medicine now or hereafter included in *materia medica*." The term "*materia medica*" is defined in Webster's New International Dictionary, 1926 edition, as follows: "1. Material or substance used in the composition of remedies: a general term for all substances used as curative agents in medicine. 2. That branch of medical science which treats of the nature and properties of all the substances employed for the cure of diseases; one of the two branches of pharmacology." For the present purpose, the court said, it makes little difference which of these two meanings is to be given the term as used in the chiropractic initiative. Taking it in either sense, the effect of the prohibition cannot be evaded by mixing one of the included drugs or medicine with something else and calling it, whether rightly or wrongly, a proprietary medicine.

The appellate court could find no error in the record, and the judgment of conviction was affirmed.—*People v. Fowler* (Calif.), 84 P. (2d) 326.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Electrocardiographic Changes Induced by Taking of Food: Preliminary Report. M. Gardberg and Jenny Olsen, New Orleans.—p. 725.

Significance of Rheumatic Activity.—The method of separating patients with active rheumatic heart disease into classes of increasing degrees of activity that Juster outlines is based on the percentage of abnormal leukocyte counts in each patient. Patients placed in the inactive group comprise those whose counts are within the normal range. Beginning with the inactive group and proceeding through the groups of first, second and third degree activity there is a progressive increase in the range and in the average leukocyte counts. The average age of the patients in the inactive and first degree groups is higher than that in the second and third. Rheumatic activity is more intense in patients in the third degree group and least in those in the inactive group. The activity of the rheumatic process is least during the summer of each year. There are symptomless periods in patients with third degree activity. In patients in whom the deviations from a normal leukocyte count (less than 9,000 cells) are 10 per cent or less the disease is considered inactive; the others are divided into three groups, depending on the amount of the deviation. The degree of abnormality depends on the percentage of abnormal to the total number of counts. For example, a patient exhibiting abnormal leukocyte counts to the extent of 50 per cent of his total number of counts would be classified as second degree.

Angina Pectoris in the Negro.—Weiss studied the records of 324 ambulant indigent Negroes with essential hypertension, including only adults more than 20 years of age, who were admitted consecutively to the outpatient department of the Louisville City Hospital, and compared them with 246 similar white patients admitted to the clinic during the same period. A history of angina pectoris was obtained in nine, or 2.8 per cent, of the Negroes and in twelve, or 4.8 per cent, of the white patients. Thus the incidence was low in both races. The author believes that explanations of the rarity of angina pectoris in the Negro are inadequate because they do not take into account the fact that there is a similar low incidence in white patients who are of the same intellectual level. A lack of ability to describe and interpret fully the sensation of cardiac pain can entirely explain the infrequency with which the syndrome is encountered in the Negro. This is the same explanation offered by Hanman to account for the social differences in the incidence of angina pectoris. The most satisfactory histories of angina were obtained from patients who were above the intellectual level of the average patient attending the outpatient department. The economic depression necessitated their admission to a free

clinic. While a disturbed emotional state can precipitate an anginal attack, a more than moronic intelligence is required to describe that attack. A difference in nervous system sensitivity seems a plausible explanation. Both white and Negro patients who attend the same clinic cannot have a low threshold for those stimuli, such as effort, cold, mental strain and excitement, which precipitate an anginal attack in an intelligent white person. No racial difference in the incidence of advanced degrees of coronary sclerosis or myocardial infarction in 177 Negro and 178 white persons with essential hypertension was found at necropsy.

Hormone Therapy of Male Breast Hypertrophy.—In view of the possibility that hypertrophy of the male breast might be due to a deficiency of the male sex hormone, Hoffman in 1935 treated six patients by injections of gonadotropic substance. Injections were given at weekly intervals over periods ranging from two to ten months. No consistent results were obtained, and the experiment was abandoned after one year. In 1937 an experiment was begun to determine the effect of injections of male sex hormone into thirty-one boys or men with unilateral or bilateral hypertrophy of the breast. Testosterone acetate and testosterone propionate were the preparations employed. The youngest patient was 11 and the oldest 73 years of age. Twenty-eight of the thirty-one patients, with various degrees of hypertrophy, received injections twice a week. The remaining three patients, who were the youngest in the group, with the smallest masses of mammary tissue and a history of beginning regression, were excluded from the experiment. The dosage employed in the first six patients was 5 mg. of testosterone acetate twice a week. After six months the dosage in subsequent cases was increased to 25 mg. twice a week, when it became evident that the smaller dosage produced no testicular damage or arrest of the normal changes of puberty. Among the twenty-eight patients who received injections of testosterone there was complete regression of the mass in fourteen, while the degree of regression exceeded 75 per cent in nine. The elapsed time before complete regression occurred varied from two to five months, and the number of injections averaged twenty-eight. In general the response was relatively rapid in the beginning. It was not unusual to note a regression of 50 per cent during the first four weeks of treatment. After the mass had been reduced to a diameter of 1 or 2 cm. the rate of regression was much slower. Sometimes this persistent residual nodule would remain unaffected for many weeks. Then, if all injections were stopped, it might disappear within a month. There was a complete failure to reduce the size of the mammary mass in two cases. In both instances the size of the breast increased despite treatment over a long period. In at least two instances there was a recurrence of the condition, which, how-

ever, responded to a second course of treatment. A mass developed in the opposite breast in one other patient while the first mass was regressing. This second mass regressed two months later, after a series of sixteen injections.

Tuberculosis Case Finding Program.—Douglas and Harmon present the data from the first eighteen months of activities in finding cases of tuberculosis under the medical participation plan of Detroit. In summary they state that: 1. Of the 114,831 tuberculin tests reported by 705 individual physicians, 27.8 per cent were considered to be positive. 2. Sixty-four physicians reported 27,084 x-ray examinations. 3. These tests and examinations resulted in the finding of 633 verified cases of active tuberculosis. 4. Approximately 2 per cent of the positive tuberculin tests related to persons found to have active tuberculosis. This percentage was independent of age and residence. 5. Of the tuberculin tests stated by the physicians to relate to contacts, 40.9 per cent were positive. Of those relating to suspects, 32.5 per cent were positive and 26.5 per cent of those not related to either of these classes were positive. 6. The percentage of positive tests increased with age, reaching a maximum of 50 per cent at about 50 years of age. 7. Of the cases of the adult type of active tuberculosis discovered, 29.9 per cent were defined as being in a minimal stage. 8. If the adult type of active tuberculosis is considered, the percentage of minimal cases declined with increasing age. 9. Some evidence was obtained which indicates that within the poor district there was no marked difference from one subdivision to another in the incidence of tuberculosis as judged by the tuberculin test.

Mottled Enamel and Water Supply.—Dean and McKay studied the effect, in three of the 375 known areas in twenty-six states, of changing the common water supply from one containing enough fluorides to produce mottled enamel to one practically free from such contamination. Each community presented the indispensable conditions of a susceptible population (children the crowns of whose permanent teeth were calcifying) using the "new" water supply and a sufficient lapse in time (from eight to ten years) for a study of the consequent differences. In Oakley, Idaho, the incidence of mottled enamel in seventy-eight children was 100 per cent before the change of water. Approximately seven and one-half years after the change in the common water supply, Oakley was resurveyed and the twenty-four children born since the change in the water supply showed normal calcification in those permanent teeth which at that time had erupted. Sixty of the sixty-two children of continuous residence at Bauxite, Ark., examined showed mottled enamel, generally of a severe type. Although the homes of the two children classified as normal were piped for the city

water, it appears that it was used only occasionally for domestic purposes. A resurvey at Bauxite ten years after a change of water supply showed that, of the forty-five children born since the change, only two showed even the mildest form of mottled enamel. At Andover, S. D., the 800 foot artesian well supplying the city water failed and the residents resorted to a well 22 feet deep. An examination of the school children ten years after this enforced change showed that the fourteen children from 6 to 10 years of age presented normal calcification of the permanent teeth, while previous to this mottled enamel was endemic.

Phrenic Nerve Interruption.—Cutler presents the results of phrenic nerve surgery in a consecutive series of 122 private white adults under care for pulmonary tuberculosis for varying periods during the last nine years and on whom one or another type of phrenic nerve interruption was performed. In 106 patients the operation was carried out as an independent collapse measure. In the remaining sixteen patients it was employed in a supplementary capacity. These patients, the author believes, represent a fair cross section of the type of tuberculous patient in whom phrenic nerve surgery has been used, as many stages and varieties of tuberculosis were present. In sixty the operation was on the left side and in sixty-two on the right. In sixty-five the phrenic nerve interruption was temporary and in fifty-seven it was permanent. The intelligence, cooperation and morale of these patients were on a higher plane than one usually encounters in clinic patients. By limiting the study to such a selected group the results represent the more favorable side of phrenic nerve paralysis. More than 50 per cent of the patients were under observation for from two to eight years. The experience gained from this series, considered in the light of a critical review of the literature, leads the author to the following conclusions: 1. The value of phrenic nerve interruption will in large measure depend on the type of case selected for the operation. Little or no good will follow the operation in many unselected cases. In from 3 to 5 per cent it may actually do harm. 2. As an independent collapse measure, the operation should not be undertaken in the presence of tuberculous lesions of the following character (unsuitable cases): apical cavities 3 or more cm. in diameter, large cavities with walls adherent in the axillary region, pneumonic consolidations, dense fibrotic lesions with embedded cavities and acute infiltrations. 3. Cases other than these may be considered "apparently suitable" in that good results will follow operation in a significant percentage of cases. This "apparently suitable" group makes up about 70 per cent of tuberculous cases. 4. No benefit will ensue from the operation, when used as the sole collapse procedure, in more than half of the cases considered "apparently suitable." 5. In approximately one fourth of the "apparently suitable" cases, improvement will follow as a result of the operation. In about 40 per cent of such cases the initial improvement in the lung subjected to operation was followed in time by serious relapse, and in 60 per cent some other form of collapse therapy was necessary to attain maximal stability of the lesion or closure of a cavity. 6. In only 20 per cent of the "apparently suitable" cases did the disease in the lung with the paralyzed diaphragm clear or undergo such stabilization that no further therapy was required. 7. There is no way of selecting this 20 per cent of patients from among the "apparently suitable" type, except through trial and error. Should the operation be unsuccessful, not only is valuable time lost, but the time lost may prove to be disastrous. 8. For these reasons, phrenic nerve interruption should not be carried out as a

choice therapy in patients in whom more certain collapse procedures can be instituted. 9. Both temporary and permanent phrenic nerve interruption have their place in collapse therapy. A temporary phrenic nerve interruption is indicated in an emergency and when other collapse measures, such as pneumothorax or thoracoplasty, are in prospect. A permanent phrenic nerve operation is indicated when the operation is carried out as the sole therapeutic measure in the attempt to cure the patient after other collapse procedures are considered unsuitable or are contraindicated. 10. The danger is not that too many phrenic nerve operations will be performed or that they will be undertaken in an indiscriminate and unthinking manner, but that the operation will be discarded. This would be unfortunate, for phrenic nerve interruption appears to have value in from 15 to 25 per cent of tuberculous patients. At times it may be the simplest means for saving a patient's life.

Reestablishment of Pneumothorax.—By incorporating the aid of some of the leading tuberculosis institutions of the country Rest collected 135 cases in which an attempt was made to reestablish pneumothorax. In fifty-two of these it was reestablished successfully. Of the fifty-two successful cases there were adhesions in forty, there were none in seven, and this was undetermined in five. The period of time for which pneumothorax was maintained before it was discontinued varied from less than one year in twenty-one cases to more than six years in one. Some of the reasons for discontinuing pneumothorax in these fifty-two cases were obliterative pleuritis, poor collapse, discontinued by patient, adequate collapse at the time and contralateral spread. The reasons for reestablishing the pneumothorax were that some of the patients had reactivation, inadequate collapse, an increase in symptoms, to replace effusion, positive sputum or hemoptyses. The author states that the reestablishment of pneumothorax is possible more often than was formerly believed and that it should always be tried when further compression is desired. The long duration of a pneumothorax and the interval after a pneumothorax was abandoned are no contraindications for reestablishment. Finally, reestablishment of pneumothorax, although possible, is far from a general attainment. Consequently, as pulmonary tuberculosis is characterized frequently by relapse, it seems plausible to continue pneumothorax indefinitely and to consider its abandonment with reluctance.

Treatment-Resistant Syphilis.—During the six years ended June 1, 1937, among the 694 patients with primary and secondary syphilis admitted to the syphilis clinic of the Stanford University School of Medicine, Beckh and Kulchar state that fifteen were resistant to treatment. They also include three other patients observed elsewhere. In all resistance occurred during therapy. The state of nutrition of all patients was fair or good. Of none was the syphilitic infection complicated by other disease or pregnancy. There was no unusual history of past illnesses. Three of the ten patients on whom such data

are available used alcohol in large amounts. The period of observation varied from eleven to seventy-three months, the average being 32.3 months. After the appearance of resistance to treatment the patients were followed for from three to forty-seven months, an average of 19.4 months. All except one patient received heavy metal therapy either simultaneously or in alternation with the arsenic medication. The clinical manifestations of treatment resistance were variable and for the most part involved the skin and mucous membranes. The lesions were for the most part similar to those usually seen in early syphilis. Three of the eighteen patients were refractory to treatment from the beginning (primary treatment resistance). In two the initial lesions were resistant to treatment but eventually involuted, only to be followed by refractory recurrences (primary-secondary treatment resistance). The original lesions of the remaining thirteen patients responded normally to treatment, the clinical manifestations of resistance appearing subsequently (secondary treatment resistance). Treatment resistance first appeared during the simultaneous phase in all the thirteen patients who received combined therapy. Among the three patients receiving the alternating type of treatment resistance occurred first during arsphenamine medication in one; data as to the phase of treatment are not available for the other two. All, however, were subsequently refractory to both arsphenamine and bismuth medication. The single patient who received only neoarsphenamine was not given heavy metal therapy during the resistant state. One patient showed resistant lesions while receiving bismarsen and failed to respond to subsequent injections of iodobismutol with saligenin. It appears that, among the patients of the present series, specific drug fastness is not an important factor in treatment resistance. While negative Wassermann reactions in treatment-resistant syphilis are reputedly common, seronegativity was encountered but once among the eighteen patients. Conjugal treatment resistance has been cited as evidence for a treatment-refractory strain of *Spirochaeta pallida*. The infected sexual partners of four of the eighteen patients were examined. The response to treatment of all four was normal, and no evidence of the transmission of a treatment-resistant strain of *Spirochaeta pallida* could be found. The data on the effectiveness of various measures used in the treatment of resistant syphilis indicate that a change of drug is the most effective treatment for refractory syphilis, but, as this measure was used with greater frequency than others, no direct comparison can be made. Similarly, as only a few of these patients were treated with fever therapy and the measure was reserved for those who were refractory to other types of treatment, its relative effectiveness cannot be fully evaluated. However, the results do suggest, in accord with the experience of others, that continuation of the treatment used before the clinical appearance of resistance is a relatively ineffectual measure. From clinical and experimental data it seems likely that the more frequent occurrence of treatment resistance among the patients given "combined" therapy is due at least in part to prolonged underdosage with the arsphenamines. However, some as yet undefined intrinsic host factor may also play a part.

Iodocholeate.—Because iodocholeate proved itself superior to tincture of iodine in laboratory studies, Lever used it in the treatment of mycotic infections of the human skin. It appeared that improvement is obtained sooner than with other fungicidal agents. The author used the clinical appearance of the lesions as the sole criterion of improvement, because it was found that the apparent disappearance of fungi from the lesions was an unreliable index. Often the fungi became undemonstrable after even indifferent treatment without clinical cure. In many cases of clinically clearcut mycotic infection he was unable to demonstrate the fungus, usually because the patient came under treatment after some time of self medication. He found that, if iodocholeate ointment is used, the most desirable concentration is 2.5 per cent; whereas, if the solution is used, 1 per cent is often sufficient, as the solution brings the iodine in more intimate contact with the skin. When the disease is resistant the 2.5 per cent solution may hasten improvement. Irritation was only occasionally observed after prolonged use of the 2.5 per cent solution. Especially good were the results in those mycotic infections in which there was maceration with oozing, because of the drying and astringent effect of the iodocholeate solution. Both ointment and solution were applied

three times a day. If the solution was used, no protecting bandage was necessary, as the solution dried soon on the skin and left a thin film. This is convenient when the patient is ambulatory. If the ointment was used, a bandage was applied. It proved valuable in some cases to use the solution twice during the day and the ointment at night. If the disease is in the acute inflammatory stage, however, or if there is secondary infection, it is well to treat the lesions for a few days with boric acid or compresses before starting the iodocholeate treatment.

Laughlen Test in Diagnosis of Syphilis.—Lever and Massie compared a series of 780 Laughlen tests with the Hinton, the rapid Hinton, the Wassermann and the Kahn test. The Laughlen test was found to be easy and fast (from fifteen to twenty minutes to perform). The reading of the test is relatively easy for those who have had experience with it. The sensitivity and specificity of the Laughlen test warrant its use as an emergency test in preference to any other test performed in this series. Compared with two other rapid tests, the Laughlen test was found less sensitive but more specific than the rapid Hinton and less specific but more sensitive than the Kahn test.

Concealed Alcoholism in Surgical Patients.—Foster discusses some facts about surgical patients who may be said to be suffering from a condition that he calls concealed chronic alcoholism. He emphasizes the need of recognizing all types of alcoholism in patients with surgical conditions and illustrates this need by reporting eight such cases. For the patient with a condition requiring surgical intervention who denies, understates or conceals his alcoholic habits, an unusual series of events often follows. Complications or sequelae may occur that commonly do not occur in the case of the abstainer. There will often be at some time in the course of his condition evidence of loss of cerebral stamina; that is, his nervous system may show instability at various points. Treatment consists in appreciating the importance of the alcoholism early; in the course of surgical treatment and in the prescription of alcohol in addition to the commonly used sedatives before dangerous depression or complications have set in. Vitamin medication is indicated preoperatively and postoperatively. A new and arbitrary (but indicated) rule of including in the first diagnosis of the condition of the surgical patient the possibility that concealed chronic alcoholism (or a tendency toward alcoholism) is present would guarantee the patient a safer course during hospitalization. Much can be learned from a patient as to the possible presence of concealed chronic alcoholism by a careful recording of detailed histories, a complete physical examination and close observation for changes in physiognomy and general physical appearance; also, by a careful noting of numerous incongruities, various endocrine activities and evidences of mental and emo-

tional instability. The surgeon should consider the possible role of alcohol in every patient that he observes. All but two of the eight patients that the author encountered were aided by small doses of alcohol.

Osseous Changes in Venereal Lymphogranuloma.—There is much evidence of the constitutional nature of infection with venereal lymphogranuloma and for this reason Wright and Logan report two apparently proved cases of bone necrosis associated with venereal lymphogranuloma and a third case in which such an association is highly probable. The literature reporting osseous and articular lesions associated with venereal lymphogranuloma has been critically reviewed by them. In the early phases of the disease arthritic and polyarthritic manifestations may occur, although they are not especially common. Chronic arthritis may occur late in the disease. Except for cases of arthritis, hydrarthrosis and pyoarthrosis, no instances of actual destruction of bone were found. They believe that lymphatic involvement with perilymphatic reaction is a possible explanation of the destructive lesions of the pubes in two of their patients. The close proximity of the inguinal glands, with their massive infection to the pubes, suggests the possibility that the infection spread by direct extension.

Bronchiectasis, Tuberculosis and Sinusitis.—Chipman and Collins declare that there is a close relationship between sinusitis, pneumonitis and bronchiectasis and that a more accurate diagnosis of sinus infection should be made early in life and every effort made to provide adequate treatment. It is difficult to evaluate the relationship of sinusitis in tuberculosis or the influence of a preexistent upper respiratory infection as a factor in the cause of a breakdown. They state that for many years the medical staff at the Saint John Clinic for Tub-

culosis encountered a group of cases characterized by symptoms suggestive of tuberculosis but found on examination to be nontuberculous infection usually associated with sinusitis. The patients presented themselves with a definite symptom complex consisting of fatigue (often intensive and seemingly out of proportion to their physical appearance), some loss of weight, a throaty or clearing cough, loss of appetite, headache and a persistent low grade fever. With these symptoms there was a history of frequent colds of the head and chest that seemed to merge into one another over a period of three or four months, especially in the fall and winter. They had cough and sputum that persisted throughout this period. During the seven years from 1931 to 1938, 4,005 new patients were examined in the Tuberculosis Clinic; 2,670 were found to be nontuberculous. From these 597 were selected as presenting symptoms indicative of sinusitis, their nasal passages were examined and when roentgenograms of the paranasal sinuses were made 352 showed definite evidence of sinusitis.

Nephrolithiasis Occurring in Recumbency.—Pulvertaft has encountered sixty cases of nephrolithiasis occurring in recumbent patients; thirty-three males and twenty-seven females. The average age was 19 years; the oldest patient was 56 and the youngest 3½ years of age. The average period of recumbency was nine months; the longest period was five and one-half years and the shortest five weeks. There can be little doubt that stagnation in the renal pelvis is an important factor in the formation of these stones. In its early stages the renal

calculus of the ambulatory patient is usually located in the lower calices or pelvis. Prolonged immobilization is followed by general decalcification of the skeleton. In the early stages of formation calculi are often little more than thin deposits on the renal walls, and they rapidly disintegrate on movement or change of posture. Rigid fixation effectively preserves these early concretions until consolidation has occurred. The calculus due to recumbency usually shows itself in either one of two ways: it may be discovered during routine x-ray examination before the development of symptoms, or change of posture may be followed by an attack of colic or hematuria. In 38 per cent of the author's cases, roentgenograms revealed calculi before their presence was suspected. In 54 per cent, hematuria or colic, or both, drew attention to the kidneys. The abdominal pain that follows a renal or ureteral distribution on change of posture has been mistaken for appendicular colic. Secondary infection may be the sequela of stone formation, and in a small group of cases (7 per cent) pyelitis or pyuria led to the diagnosis of a stone. Patients who need to be recumbent for long periods should undergo postural treatment, and routine x-ray examinations should be done of the renal tracts. Some of these calculi that occur in recumbency disappear when the erect posture is resumed, but many remain and these may require surgical intervention. The complication may be fatal. Some means must be devised to overcome the defective drainage of the kidneys. A simple method is bed tilting.

Vertebral Lesions in Undulant Fever.—Bishop reports the fifty-seventh case of spondylitis complicating undulant fever. *Brucella suis* was isolated from the blood soon after the local lesion developed, which occurred more than a year after the initial infection. The lesion in the lumbar region was treated by surgical fusion, and the cervical lesions by support (head traction), with improvement after seven months. Clinically, hematogenous localization of bacteria occurs, ordinarily in the osseous marrow, but exceptionally in the disk in young persons. X-ray examination reveals a spreading process of the infiltrative type in which there is a reactive phenomenon, proliferative in nature and characterized by endosteal and periosteal reaction. The result is sclerosis of the body with hypertrophic spur formation. There is little tendency to invasion of the paravertebral tissues. This complication originates usually in the convalescent stage of undulant fever but may make its appearance at any time. It is accompanied by a febrile reaction and is characterized by the acuteness of the symptoms and a benign clinical course. Recovery is the rule.

Poliomyelitis and Lymphatic Apparatus.—Yoffey and Drinker carried out experiments to determine whether virus (Toomey T strain) could ever be detected in the cervical or the thoracic duct lymph of monkeys. They also endeavored to produce the disease by the injection of virus into lymph nodes and by rubbing it into the taste buds. The results of the experiments show that virus is not present in cervical lymph imme-

CURRENT MEDICAL LITERATURE

718

diately after nasal instillation, after paralysis has developed or after infection has taken place but before the onset of paralysis. Virus is not present in the thoracic duct lymph of paralyzed animals. Infection is not produced by injecting virus into lymph nodes or by rubbing virus into taste buds. Since the results have been so consistently negative the authors conclude that the strain of virus employed does not spread by way of the lymphatic vessels and nodes or else that it is present in concentrations below the minimal infective dose.

Cerebral Blood Flow in Epileptiform Seizures.—Penfield and his colleagues observed that in chronic epileptic subjects focal fits may be induced by electrical stimulation of the cortex which are outwardly identical with the habitual fits of the patient in question. During the seizure there is an increase in circulation within the circumscribed area of cortex which is involved in the "discharge" that produces the fit. This increase begins within the first minute after the precipitating stimulus with no preliminary decrease in flow and it outlasts the clinical evidence of the seizure. In animals epileptiform seizures were accompanied by a constant circulatory increase in the motor cortex (using the term motor broadly). A similar but more marked increase has been observed in the caudatum, putamen, pallidum and thalamus. This blood flow increase appeared to be limited to the contralateral hemisphere in cases of unilateral convulsion. In generalized convulsion the change was equally present in the two hemispheres. This increase in circulation started a few seconds after the first muscular movements and

Monoethanolamine Salt of Ascorbic Acid for Vitamin C Deficiency.—Lozner and his associates find that the intramuscular injection of the monoethanolamine salt of ascorbic acid presents a simple and effective way of administering vitamin C parenterally when need for this type of injection is indicated. There were no immediate or delayed, local or systemic reactions following its use in the three patients to whom it was administered. Its intramuscular administration was followed by a prompt increase in the vitamin C content of the blood. The loss of vitamin C in the urine was not as marked as when crystalline ascorbic acid was given intravenously. A patient with marked vitamin C deprivation was saturated in eight days by the daily intramuscular injection of 100 mg. of the monoethanolamine salt of ascorbic acid.

Postpuncture Reactions.—Davenport obtained follow-up data after 178 cisternal and 681 spinal taps. Significant postpuncture reactions developed in eighteen cases in which cisternal punctures were done, and in the 681 spinal punctures averaged postpuncture headaches developed in 223 cases. Reactions to cisternal puncture were much milder; only two reactions lasted longer than three days. Spinal puncture reactions averaged 4.32 days. A relationship between race and the incidence of reactions was shown in the case of spinal punctures. The percentage relationship was Negro 27.04 per cent, white 32.9 per cent and Puerto Rican 43.1 per cent. A relationship between sex and the incidence of reactions was males 28.9 per cent and females 43.9 per cent. A relationship between neurosyphilis and the incidence of spinal puncture reactions was seen, tending to bear out the tradition that postpuncture headache usually indicates a negative spinal fluid or but minor changes in the cerebrospinal axis. Neurosyphilis was present in 22.4 per cent of the cases in which reactions occurred. Postpuncture headache was 95 per cent assurance that the spinal fluid was negative or cerebrospinal involvement was of mild degree.

Smallpox Vaccination.—Ellis and Boynton give the results of the vaccination against smallpox of 9,086 students at the University of Minnesota during the years from 1936 to 1938. Prior to admission to the university 83 per cent of these students had been vaccinated successfully. Three kinds of vaccine were used, two cultured artificially by the methods of Rivers and Goodpasture, respectively, and one prepared by the usual calf method. The Rivers vaccine was employed intracutaneously, the Goodpasture both intracutaneously and by multipuncture and the calf vaccine was used only by multipuncture technic. The calf lymph virus gave a higher percentage of primary takes than the other two types of virus. However, the results with the Goodpasture vaccine when used intracutaneously were not grossly inferior to those obtained with calf lymph. Severe local and constitutional reactions following vaccination were slightly less frequent with the Goodpasture vaccine than with the calf lymph vaccine and severe local and constitutional reactions were reported more frequently with the Rivers vaccine than with any other type of vaccine. Immune reactions were encountered in more than 61 per cent of students who had never been vaccinated successfully and who had never had smallpox. A majority of these students had been vaccinated many times.

Roentgen Irradiation for Acute Otitis Media.—Dowdy and his colleagues compare the results obtained in thirty cases of acute otitis media treated with one or more doses of 100 roentgens and twenty-six unirradiated controls. Even these small doses of x-rays seemed to be of distinct value in relieving the acute symptoms and in shortening the course of the disease. The average duration of the disease for the acute, purulent, uncomplicated cases was shortened by six days, while that of the complicated cases was shortened by sixteen days. The

clinical improvement when the treatment is effective is still more striking. The incidence of surgery appeared to be reduced. The treatment is a conservative method, since it does not interfere in any way with other indicated forms of treatment, and the dosage used causes no permanent damage. As with other forms of treatment, better results are obtained in the early stages of the disease.

Roentgen Therapy for Sinus Infections.—Hodges and Snead believe that sinus disease is far more prevalent than is usually realized, that because of the meager symptoms its diagnosis is being overlooked in most instances, that the treatment is frequently inadequate and that in many instances no accurate method of checking the results of treatment is being used in a routine way. Since almost every patient should be seen by both the rhinologist and the roentgenologist for diagnosis and follow-up of the results of the treatment, a whole-hearted and sincere cooperation between them is absolutely essential. The authors are more enthusiastic than ever before over the results that can be obtained by irradiation in the treatment of certain types of infections of the nasal accessory sinuses. 1. Acute sinusitis, with good drainage, will generally clear up fairly quickly under the usual treatment of astringents, packings and washings. In these cases irradiation is not necessary unless it is used to hasten recovery. 2. Cases of subacute or subchronic sinusitis respond best to irradiation. Symptoms in this type of case have been present for from several months to several years; usually there is a cough and a history of recurring colds and the patient has been under the care of one or more rhinologists. Washings cause little or no change in the appearance of the antrums. In many of these cases the bronchovesicular shadows of the lower lobes are exaggerated. 3. In the third group of cases symptoms have been present for several years, usually with hyperplastic sinusitis. There is marked cloudiness of the ethmoids and marked thickening of the membrane in the antrums. Usually the longer the duration of the infection, the poorer the result. The majority of these cases have also responded to irradiation. 4. The fourth type consists of early or reasonably early polypoid changes, especially in the nose, with a history of infection for many years. The majority of these patients experienced marked relief from irradiation. In a number the sense of smell was reestablished and two have had marked improvement in vision following treatment. Others, who were unable to breathe through the nose at all, have been relieved in this respect. Some who had to have repeated operations for removal of polypoid material from the nose have had no recurrence of this. 5. Old, exceedingly chronic polyp formation, usually widespread, is present in the fifth and last type of case. Only a small percentage of these patients receive much benefit from irradiation. In a few cases of from fifteen to twenty years' duration, however, definite benefit from treatment has been experienced. The first three groups have been treated with 130 kilovolts with 6 mm. of aluminum filter, about 300 roentgens. This is given in three or four treatments, over a period of from one to three weeks. Children have been given smaller doses. The remaining groups have been treated with 200 kilovolts with from 0.5 to 2 mm. of copper filter, 600 roentgens. To the second and third group of patients, with cough and an increase in the bronchovesicular shadows of the lower lobes, small doses of radiation were also given over the lungs.

Endocrine Dyscrasias Associated with Conduct Disorders.—In view of the contradictory and confusing reports regarding the relationship, or lack of relationship, between behavior disorders in children and the various types of endocrine dyscrasias, Gydesen and Murphey reviewed sixty-four cases that had been examined by a child psychiatrist in a child guidance clinic and also by an endocrinologist in private

practice. Thirty-six of these children were referred to the endocrinologist by the child guidance clinic as cases presenting a possible endocrine dyscrasia. The thirty-six cases were selected from a series of 313 consecutive full-study cases examined in the child guidance clinic. Thyroid (thirty-two) and pituitary (eighteen) disorders were by far the most common conditions discovered. All the children specifically treated showed definite improvement in their school and social adjustment with endocrine therapy.

Papillary and Lateral Aberrant Thyroid Tumors.—

Crile reports twenty cases of papillary carcinomas of the thyroid, fifteen cases of papillary adenomas of the thyroid and thirteen cases of papillary tumors arising in lateral aberrant thyroid tissue. In only five of the papillary carcinomas has death occurred as a result of the tumor. In no instance has it been proved that either regional or distant metastasis took place. In nearly half the cases of lateral aberrant thyroid disease the lobe of the thyroid on the affected side contained a tumor histologically identical with the lateral cervical nodules. It is often difficult to distinguish between multiple lateral aberrant thyroid tumors and metastatic papillary carcinoma in cervical lymph nodes. It is probable that many cases reported as papillary carcinoma of the thyroid with metastasis to the regional lymphatics are in reality benign papillary lateral aberrant thyroids with a coexistent benign tumor in the thyroid. Tumors arising in lateral aberrant thyroid tissue are essentially benign. Only two of the forty-five patients classified in the literature as having malignant tumors of lateral aberrant thyroid origin have been reported to have died as a result of recurrence of the tumor following operation. None of the thirteen patients in this series have died as a result of lateral aberrant thyroid disease. Surgical intervention is the indicated treatment for all papillary tumors of thyroid and lateral aberrant thyroid origin. Roentgen therapy has not proved effective.

Prostigmine for Intestinal Atony and Urinary Retention.—Since the value of prostigmine in the treatment of paralytic ileus is well established, Marden and Williamson used it in preventing the postoperative occurrence of intestinal atony and urinary bladder retention. Of 253 operative cases, 250 were studied for intestinal distention and 247 for urinary bladder retention. Three of the cases involved such surgical procedures

as first stage colostomy and could not be studied from the standpoint of intestinal atony, and six involved operations on or near the bladder in which catheterization was routine. The patients were divided into three groups: (A) those receiving prostigmine both before and after operation, (B) those receiving it before operation only and (C) those receiving the drug after operation only. In groups A and B, when possible, three injections of prostigmine were given at convenient intervals over the period of eighteen hours immediately preceding operation. In groups A and C the administration of prostigmine was started within four hours of the patient's return from the operating room and continued at intervals of four or six hours for a total of from four to six doses, or more if distention or retention appeared imminent. The 1:2,000 solution of prostigmine in 1 cc. doses was used. In groups A and B the incidence of intestinal distention was reduced to 5.7 per cent. In group C the incidence of distention was 1.4 per cent. No ill effects resulted from the continued use of prostigmine after end to end anastomoses and other types of gastrointestinal surgery. The tone of the intestine was observed at operation to be much better in those patients who had received prostigmine before operation. In the urinary retention series, patients receiving prostigmine before operation required catheterization in but 3.9 per cent of cases, while 6.9 per cent of those receiving the drug only after the operation had to be catheterized. Some patients, during the twelfth and eighteenth postoperative hours, experienced a desire to void but were unable to do so until later. To aid these patients, in addition to the regular routine doses, 1 cc. injection of 1:2,000 prostigmine was given every hour for three injections. This resulted in the most gratifying response. Most of the patients voided after the first or second injection and in no case was catheterization necessary. No patient in the combined series exhibited any marked lowering of the blood pressure or slowing of the pulse. There was no appreciable degree of miosis, impairment of accommodation or sweating. This is in agreement with the observations of other investigators. Some patients received as many as twenty-four 1 cc. doses of 1:2,000 prostigmine. Subjective complaints were rare and "gas pains" were infrequent.

Etiology of Acute Rheumatism.—Green examined the pericardial and valvular lesions of nine cases of primary or recurrent rheumatic carditis post mortem and for a control study he also examined the same tissues from a group of nonrheumatic subjects. From eight of these cases he recovered hemolytic streptococci from the heart valves with vegetations and from the pericardial lesions. This organism was present in pure culture in seven valves. In six others coliform organisms were also present, and in one case *Streptococcus viridans* and *Streptococcus haemolyticus* were both obtained. No growth was obtained from three of the remaining five valves with vegetations, one yielded *Streptococcus viridans*, and one was not cultured. As controls, twelve valves without macroscopic lesions from these same hearts were cultured and in no instance were hemolytic streptococci recovered. Coliform organisms were obtained in three valve cultures and *Streptococcus viridans* in one, the remaining eight being sterile. The heart blood was sterile in six cases of the rheumatic series, coliform organisms were present in two, and in one instance this control was omitted. Any possibility that the presence of hemolytic streptococci was the result of contamination from some source other than the tissues of the bodies under examination was excluded in that the streptococcus recovered from the cardiac lesion in five cases was of the same serologic type as the strain isolated from the individual patient's throat before death. Further, when hemolytic streptococci were isolated from more than one valve the strains were serologically identical. In the twenty-two nonrheumatic cases coliform organisms and hemolytic streptococci were both recovered from the heart valves in a case of postoperative peritonitis, while in one case of bronchopneumonia hemolytic streptococci were obtained in pure culture from the heart blood and heart valves. In both cases the pericardial cultures remained sterile, and all the heart valve cultures yielded growths of hemolytic streptococci. As the valve inoculums were not washed free from blood, the presence of hemolytic streptococci was attributed to traces of infected blood on the valve surfaces.

Vitamin A Deficiency and Keratoconus.—Mutch and Richards produced keratoconus experimentally as a sequela to acute xerophthalmia in rats on a vitamin A-free diet. In most cases the corneas regained their normal contour after the animals were given vitamin A for a few weeks. Corneal nebulas and myopias remained as permanent defects. In view of this it seems probable to the authors that, in countries in which xerophthalmia among the human population is not uncommon, varying degrees of keratoconus should be found. Chronic and low grade xerophthalmia due to suboptimal intake of vitamin A may be more prevalent than is realized. The corneas may be weakened by intermittent attacks, and permanent stretching of

the tissues may take place without obvious vascularization or other pathologic sign. Keratoconus in European countries is rare, myopia and myopic astigmatism are common; their production may be due to the same mechanism. The authors do not suggest that keratoconus is due in every case to avitaminosis A but they do know that, owing to the lack of vitamin A, ocular lesions can be produced experimentally in 100 per cent of rats and keratoconus with comparative ease. In the human child exactly similar lesions of the eyes going on to perforation are produced by vitamin A deficiency. Therefore it does not appear unreasonable to them that if a child is receiving a diet deficient in vitamin A the corneas and scleras may become weakened and unable to withstand the increased pressure when the child is eventually given an adequate diet. Keratoconus will probably not develop in the child but myopia or myopic astigmatism will, if the pathologic changes in man are comparable to those of the rat.

*Skin Eruption Caused by X-Ray Therapy on Endocrine Glands. Sylvia Bray.—p. 312.

Cutaneous Eruption from Roentgen Therapy of Endocrines.—Bray discusses the occurrence of seven cases of an unusual cutaneous eruption produced during and shortly after the roentgen treatment of ovaries, thyroids and pituitary glands. These eruptions have been encountered only during the last eight years, that is since therapeutic x-rays, produced by a voltage of 190 kilovolts and over, with filters of not less than 2 mm. of copper, have been in use. The author knows that to attribute this cutaneous eruption (an itchy, slightly raised papular red rash) to a disturbance of the hormone balance by the short x-rays on one of the components of the endocrine system is a big assumption; but it seems justified to her, as the condition has not appeared in any case in which an endocrine gland was not being subjected to irradiation. The time of the appearance of the rash has well defined limits: between three and one half to eight weeks after treatment is begun. The distribution is limited to the unexposed parts. The appearance of the rash itself from a dermatologic point of view is also constant, the chief variation being in the size of the papules. None of the patients observed had vesication and none were left with scarring. All the cases apparently responded to local treatment; but this, the author thinks, is closely bound up with the probability that the internal biochemical change causing the rash is of fairly short duration. The small number of cases occurring is rather puzzling when the large number of pelvic cases treated are considered in which the ovaries receive a large dose. There must be other individual factors, as well, which influence the production of the rash. It seems as if an immunity develops, as none of the patients had the rash a second time.

Natural Healing in Pulmonary Tuberculosis.—Under present day conditions clinical observations can receive confirmation by x-ray examination of the chest. Ellman states that clinical and x-ray observations of the chest show that any fresh tuberculous, pneumonic or bronchopneumonic process of the recent exudative type may actually heal by resolution in a manner comparable to that observed in lobar pneumonia and bronchopneumonia. However, the time factor for resolution in a tuberculous pulmonary lesion is much longer, requiring perhaps months instead of days or weeks of complete bed rest. Fresh exudates occur more particularly in the first three or

CURRENT MEDICAL LITERATURE

722

four decades of life, are largely confined to the upper lobes of the lung and tend at the onset to exhibit a general constitutional rather than a local symptomatology. In an extremely acute case massive necrosis may take place and the question of resolution does not then arise; but adult phthisis in its early manifestations is, so far as the lung is concerned, principally a localized disease and this enables the body to put up some resistance to the invasion of the bacillus. Prolonged rest, both general and local, will assist the maintenance of this naturally acquired immunity. Many lesions seen roentgenologically may closely simulate those of a tuberculous exudate. Therefore the process of their natural resolution should not be attributed to tuberculous lesions when, in fact, they may be due to such conditions as atypical resolving pneumonia of an acute, subacute or chronic nature, to suppurative pneumonitis and the like. There is a type of recent exudative pulmonary tuberculosis which will heal by natural resolution and produce permanently good results when well supervised absolute bed rest under the strict discipline of the sanatorium regimen can be obtained. Serial clinical and x-ray investigations should accompany this treatment, for, when it is apparent that spontaneous healing is taking place, bed rest with x-ray control should be encouraged; if, on the other hand, there is no progress or there is retrogression, collapse therapy can be induced. Early recent exudative lesions should in first instance be given an opportunity of healing by simple methods with careful x-ray control. Immediate collapse therapy is not always justifiable. An artificial pneumothorax that is induced prematurely may prove to be contraselective and may require yet further intervention, culminating finally in a thoracoplasty operation. On the other hand, in selected chronic bacilliferous cases surgical intervention may be the life saving factor. Surgical intervention is, after all, merely another means of reinforcing rest of the lung; therefore if complete and prolonged rest can, unaided, produce the desired results it should be the initial method of choice. The foregoing principles of the healing of noncavitating lesions apply also to cavitation, and, as a rule, retrogression of the lesion and healing of the cavities accompany each other. Generally, recent exudative cavities respond more favorably to strict bed rest. The older and more productive that a cavity is the more likely is it that some form of surgical intervention will be necessary. At the beginning, most cavities should be given the opportunity of responding to bed rest. Only if the lesion is retrogressing or remains stationary should collapse therapy be considered. The evolution of cavities is dependent on the state of the draining bronchus. Coryllos and Ornstein state that complete closure of the draining bronchus of a cavity with obstructive atelectasis is the only means by which cavities can heal, no matter what the size of the cavity or the nature of its wall. They classify cavities according to the closure or patency of the draining bronchus. The theory of the patent bronchus permitting free circulation of air into the cavity, and hence an adequate supply of oxygen favorable to the growth of tubercle bacilli, appears to be rational and enables one to postulate that cavities are either open or closed and that the latter, accompanied by bronchial obstruction, tend to heal.

*Maneuver to Facilitate Abdominal Palpation. C. H. Osborn.—p. 1086.

Abdominal Palpation.—Osborn suggests a method by which it is possible to diminish the voluntary contraction of the abdominal musculature frequently observed in whom, owing to apprehensive patients during abdominal palpation. The method is also valuable in those patients in whom, owing to pronounced lumbar lordosis or to increased intra-abdominal tension, the abdominal wall is tense and stretched. With the patient in the supine position, with the arms at the sides and the head and neck comfortably elevated on a pillow, the lower limbs are drawn up by semiflexing the hip and knee joints, and the examination then proceeds. Relaxation of any muscle is obtainable only by approximation of its points of attachment. The two major attachments of the abdominal group of muscles are

the lower ribs at the cranial end and the bony and ligamentous structures of the anterior aspect of the pelvis at the caudal end. Approximation of these points will automatically relax these muscles. This is not sufficient, in most instances, to make any appreciable difference in the tenseness of the abdominal wall. In order to accomplish this object it is necessary to rotate the pelvis on a horizontal axis which passes through both hip joints. This entails movement of the anterior aspect of the pelvis to an appreciable extent in a cranial direction and also some flattening of the normal lumbar curve. The desired posture may be secured by first placing the patient in the orthodox position, with the knees drawn up and the feet firmly placed, and then asking him to "raise his tail bone 1 inch from the couch." This position can be maintained with perfect ease, and if the hand of the examiner is placed on the abdominal wall while it is being assumed a noticeable diminution in the amount of muscular resistance will be felt immediately. By this simple maneuver it is possible materially to increase the knowledge obtainable by palpation of the abdomen. Similar relaxation may be obtained by elevating the thorax on pillows or by placing a pillow under the sacrum, or by both these measures, but such steps the author states are not as simple or as effective as the one described.

Mechanism of Metrazol Convulsions.—Watterson and Macdonald performed experiments to determine whether metrazol, after intravenous injection, has time to reach the central nervous system before the convulsion occurs. They found that after 0.5 cc. of a 2 per cent solution of sodium cyanide is injected intravenously reflex hyperpnea occurs when the drug reaches the carotid sinus. The hyperpnea is quite characteristic, consisting of two or three sudden deep inspirations; it is best seen if the subject relaxes in a semirecumbent position. In these experiments twelve cooperative patients were given intravenously convulsion-producing doses of metrazol mixed with 0.5 cc. of a 2 per cent solution of sodium cyanide. In each case the characteristic hyperpnea due to carotid sinus stimulation occurred a second or two before the convulsion began. The experiments show that the metrazol passes the carotid sinus before the convulsion begins and that the convulsion is clearly demarcated from the reflex hyperpnea. In fact, the short interval following the hyperpnea is probably long enough to allow the metrazol to reach all parts of the brain. Experiments are described which show that under appropriate conditions carbaminoyl choline, acetyl-beta-methylcholine and sodium

cyanide inhibit the metrazol convulsion. Caffeine, administered either orally or intravenously, does not inhibit the convulsion. The conclusion is drawn that cerebral vasodilatation inhibits the convulsive action of minimal convulsion-producing doses of metrazol. It is suggested that the increased rate of cerebral blood flow is the important factor in the inhibition, rather than cerebral vasodilatation by itself.

Mental Complications After Convulsion Therapy.—

On the basis of an analysis of the results of convulsive therapy for the psychoses, Dynes declares that aside from complications such as fractures, cardiac arrhythmias and dislocations undesirable mental sequelae may occur in these cases. The physicians in charge and the nursing staff were agreed that the conditions were made worse by convulsant drugs in the cases discussed by the author and that the conduct disorder and deterioration shown was out of all proportion to that ordinarily expected in cases of this type in which no form of special treatment was administered. The undesirable or unfavorable responses were of two types. One group includes three patients who became violent and difficult nursing problems for a long time after receiving convulsant drug therapy and in general showed an aggravation of their mental symptoms. A second group of seven patients showed evidence of memory failure, intellectual deterioration and confusion, not present prior to convulsant drug therapy. Some of the latter were less troublesome from a nursing standpoint, although there were others who showed intellectual impairment and were also more difficult to nurse. These ten patients make up 15 per cent of a series of sixty-eight patients treated by convulsant drugs. Nine of the sixty-eight could be considered complete remissions, twenty were at home improved, while thirty-nine remained unimproved. In these thirty-nine who were unimproved were included the ten who were actually made worse by the treatment. The patients who had complete remissions showed evidence of improvement after from one to four convulsions. Therefore there seems to be no reason why convulsant drug therapy should be continued up to twenty treatments, as irreparable damage may be done to the nervous system. Most of the patients showing adverse mental sequelae had twenty or more treatments.

Masked Hypothyroidism as Cause of Amenorrhea.—

Dodds and Robertson report five cases of secondary amenorrhea resistant to simple substitution therapy. The patients presented none of the usual features of generalized disorders known to cause amenorrhea. Determination of the basal metabolism showed that quite a marked degree of hypothyroidism was present, despite the absence of any of the classic signs of this disorder. Adequate treatment with thyroid extract caused the basal metabolism to rise to normal and this was accompanied by the establishment of normal menstruation. In one case in which the dose of thyroid extract was reduced and the basal metabolism as a result fell below normal, amenorrhea reappeared, but menstruation again returned when an adequate dose of the thyroid extract was given to raise the basal metabolism to normal.

Vitamin B₁ Deficiency in Hookworm Anemia.—McKenzie reports two cases of hookworm anemia in which a considerable degree of edema was present. Treatment with vitamin B₁ in the form of brewers' yeast and a synthetic crystalline vitamin B₁ rapidly cured the edema after treatment with iron and the provision of a generous diet had failed to do so. The administration of the synthetic vitamin B₁ was followed in both cases by increased diuresis, an action which does not appear to have been recorded from true beriberi. The result of this treatment suggests that the edema which accompanies hookworm anemia is due to a deficiency of vitamin B₁, which is in turn due most probably to loss of vitamins in the blood extracted from the host by the hookworm.

Antagonism of Quinine to Prostigmine in Myotonia.—Briscoe carried out experiments in an effort to determine whether the characteristic depressant effects of prostigmine in normal muscle were antagonized by quinine as they were by curarine. Contractions of mammalian muscle (cat's quadriceps) have been recorded isometrically. She found that quinine, injected intravenously, is antagonistic to prostigmine and synergistic with curarine in its effects on normal skeletal muscle. Quinine produces its effects on muscle both by raising the threshold of the motor end plates and by direct action on the muscle fibers. It is not possible to decide which of these two actions of quinine is the more important in the relief of the rigidity of congenital myotonia until more is known of the cause of this disease. It is suggested that in congenital myotonia there is hyperexcitability to normal amounts of acetylcholine.

Compulsive Grasping, Grasp Reflex and Tonic Innervation.—Allen studied the phenomena of grasping and tonic innervation in sixteen cases in which there were cerebral lesions. The observations confirmed the occurrence in the human subject of two groups of phenomena: labile, fully coordinated and sometimes but not always amenable to being brought under voluntary control, and a fixed pattern, arising from a constant stimulus and usually but not always insusceptible of being brought under voluntary control. The first group occurs in response to visual stimulation, to tactile stimulation or to both. Visual stimulation consists in movement toward and the grasping of an object presented at a short distance from the hand. Tactile stimulation is more effective than visual stimulation and the two together more than either of them alone. When completed, it is under voluntary control. At the beginning, however, it is compulsive. Sometimes it is controlled volun-

tarily or at command at the outset; at times it is controlled and then bursts past the control, and at others it appears at once in spite of attempts to control it. It is evidently related to integrations at the cortical level and is at least analogous to the repeated sucking response observed in one patient. The second group arises in response to stretch and appears even when visual and tactile stimulation are impossible. It is observed in the muscles of the limbs, in the hand and foot, and in the jaw. It consists in increase of muscle tone with, in the hand, a grasp which increases as the stimulation continues and, in the jaw, a traplike closure of the mouth and teeth on the stimulating object. It arises primarily and most effectively from stretch of the flexors of the thumb and index finger. It is not prevented by the patient either voluntarily or at command, but in its minor forms the grasp can be stopped and undone at command even though the appropriate stimulation continues. It is evidently operative at a level below that of the cerebral cortex. It appears that the two groups of phenomena cannot be rigidly separated and that they are mutually dependent and interact in the human subject. The position of the patient in space affects the two groups of phenomena; that is, in the lateral position it increases them in the uppermost limb and decreases them in the undermost limb. Both the first and second groups of phenomena appear to interact closely with the righting mechanism or to form an integral part of it. The term "compulsive grasping" appears to be appropriate to the compulsive phenomena forming the first group, "tonic innervation" to those of the second group, and "grasp reflex" to those of the second group in the hand.

Bacteremia and Oral Sepsis.—In his discussion of bacteremia and oral sepsis Elliott concludes that transient streptococcal bacteremias are a frequent sequela to dental extractions especially when the mouth is the seat of severe chronic gingivitis. Bacteria may also gain admission to the blood stream in such cases irrespective of operative procedures and probably as the result, in many instances, of minor degrees of gingival injury such as is produced by biting on a loose tooth. Acute apical infections do not appear to be especially associated with blood infection of this kind; the focus of infection is apparently effectively "walled off" by the associated inflammatory reaction. Of the two factors infection and trauma involved in the production of these postoperative bacteremias, infection appears to be the more important since, when it is marked, even slight trauma to the gums is sufficient to produce invasion of the blood stream. In the complete absence, however, of the type of trauma induced by the "rocking" of a tooth during its removal, extraction may be accomplished without producing a heavy bacterial shower in the blood. Usually these transient bacteremias produce no permanent ill effects, but there is some evidence that, occurring in subjects with abnormal heart valves, they may lead to subacute infective endocarditis. Thirteen cases are reported in which the valvular infection appeared to result from a postoperative dental bacteremia. Such bacteremias may be prevented by the reduction or elimination of infection and trauma. Complete elimination of gingivitis is difficult, although preliminary treatment of the margins of the gums by some measure, such as cauterization, may lessen it and lead to a reduction of the postoperative bacterial shower. Similarly, by avoiding unnecessary manipulation of an infected tooth during its extraction the incidence or degree of blood infection may be decreased.

Cleidocranial Dysostosis.—The study of five cases of cleidocranial dysostosis disclosed that the clavicular and cranial malformations are accompanied as a rule by other malformations of the bony structure, among which pelvic malformations are the most frequent with those of the face and spinal column following. In discussing the origin of cleidocranial dysostosis, Debré and his associates state that it is not connected with any infection and in particular with syphilis, that it is not a bone disease of membranous origin, that it is not connected with a malformation or lesion of the uterus or the membranes of the ovum and that it is not the consequence of an oligohydramnios. Cleidocranial dysostosis is a genotypic dystrophy which seems to be transmitted as a dominant mendelian characteristic.

Postabortal Placental Retentions.—Portes and his collaborators observed a number of total or partial placental retentions, which were tolerated for a shorter or longer time after abortion. Each time the clinical circumstances permitted, the authors verified the presence of placental elements in the uterus by endoscopy to remove under visual control fragments of presumably placental or juxta-placental tissues to make a microscopic examination; they also resorted to biologic determination of the gonadotropic hormones. The endoscopy was carried out according to the method of Segond. It was generally done without anesthesia, because the cervix uteri was permeable in most cases. Without describing all the details of the endoscopy with the aid of Segond's instrument, the authors stress that it is best to utilize, whenever possible, a hysteroscope of large caliber. The biopsies were made under visual control by employing forceps suited to Segond's apparatus. The determination of the gonadotropic hormones was done by means of the usual biologic method. The authors describe their observations on nine women. The placenta appears in the form of mulberry-like masses, red-violet and ecchymotic and surrounded by clusters of disintegrated whitish tissue, which float in the liquid and contrast with the rose colored and normal appearance of the adjoining healthy mucosa. Independently of placental masses there are observable, even in recent and noncomplicated retentions, polypoid processes of the endometrium corresponding microscopically to an infiltration of the stroma by round cells and hemorrhagic exudates and are probably of inflammatory nature. Experiences so far indicate that the hysteroscopy apparently does not reveal the débris which is attached to the uterine horns. On the other hand, the placental tissue which occupies one of the surfaces or the fundus of the body of the uterus is clearly evident. When the hysteroscopy was not immediately followed by curettage they were totally apyretic. The women, thus left in a state of retention, later expelled the retained débris spontaneously, perhaps in the course of the subsequent menstruation. Hysteroscopy is of value because it makes it possible to limit curettage to cases in which placental retention is endoscopically verified. The biologic determination of gonadotropic substances does not seem to supply useful information with respect to

vitality or even the presence of placental tissue. In eight of nine cases the biologic examination of the urine was negative with quantities below 400 mouse units, and this was so in prolonged as well as in recent retentions. The authors found that the reactions were negative likewise when the curetted placental tissue presented all the histologic aspects of vitality. This fact is perhaps explained by the absence of all vascular connections between the retained placenta and the maternal organism.

Reaction of Skeleton After Bone Fracture.—Roche and his collaborators studied the phosphatasic activity of the skeleton after the fracture of a bone. Experiments were made on adult pigeons and rats. They concerned the phosphatasic activity of the epiphysial and diaphysial regions of the fractured bone and of the intact homologue. It was found that the callus of the fractured bone generally presents the same phosphatasic activity as do the diaphysial and epiphysial regions of this bone. The considerable augmentation of the enzymatic activity which follows the fracture becomes manifest a few days after the traumatism and well before the callus is formed. The intact bones of an animal with a fracture present an augmentation of their phosphatasic activity simultaneously with those observed in the different regions of traumatized bone. The author further takes up the general modification of the composition of the skeleton after fracture of a bone. He found that a long bone with fractured diaphysis (humerus of pigeon or femur of rat) presents in the epiphysial or diaphysial regions successive modifications of composition. These modifications, which are greater in the immediate surroundings of the lesion, evolve simultaneously in all parts of the organ. They are characterized at first by a demineralization of all parts, followed by a more or less complete restoration of the losses. The intact portions of the skeleton present qualitatively the same modifications of the composition. These modifications are less intense in the normal parts than in the traumatized parts, but they can always be observed. The author reaches the conclusion that the osseous system constitutes a biologic entity in which the behavior of each anatomically individualized part is under the influence of general mechanisms regulating the development, the composition and the physiologic activity of the skeleton in its entirety.

*Prolonged Polyglobulism After Birth. J. C. Schippers.—p. 102.

Prolonged Polyglobulism After Birth.—Schippers first reports the clinical history of a child who was brought to the hospital eight days after birth. The child nursed poorly; its general condition was unfavorable and it was cyanotic. During the night before hospitalization it had had convulsions, and an intracranial process was thought of. The hemoglobin content and the erythrocyte count were high. A spontaneous hemorrhage took place into the left eyelid and this was later followed by the development of an abscess, which was incised and yielded a large amount of pus. During this time the hemoglobin content and the erythrocyte count remained high. Inhalation of oxygen was instituted and gradually the polyglobulism and the high hemoglobin values disappeared. Follow-up examinations later revealed that the blood remained normal and that the physical development of the child advanced normally, but the mental development was retarded. This case raises the question whether a connection exists between poly-

globulism and defects of the brain. After pointing out that polyglobulism occurs also during certain congenital cardiac defects generally resulting from insufficient oxygenation of the blood, and after saying that there are also cases of idiopathic familial polycythemia, the author says that the literature contains numerous reports on the appearance of polyglobulism as the result of a pathologic process in the brain. It is doubtful that the cerebral anomalies are the cause of the polyglobulism, because the status of the blood has become normalized whereas the cerebral defect remains. When the polyglobulism is primary, the cerebral disorder can be considered as a result of thromboses of certain cerebral vessels. After citing several authors who have described thromboses provoked by polyglobulism, Schippers describes several other case histories of prolonged polyglobulism after birth. He says that Baar and Stransky attribute it to a hyperactivity of the bone marrow but that signs of hyperactivity of the bone marrow were apparent in none of his cases. He regards as the most natural explanation a retardation or an imperfection of the hemolysis, which commences immediately before birth and which is noticeable during the first days of life. The fetus suffers from an insufficiency of oxygen, and when respiration begins the erythrocytes disappear under the influence of the abundant supply of oxygen. The change of hemoglobin into bilirubin may provoke the appearance of icterus neonatorum. The author considers it noteworthy that none of his patients with prolonged polyglobulism presented this form of icterus. Moreover, their polyglobulism disappeared after the administration of oxygen. The fact that hemolysis begins already before birth suggests that other factors besides the oxygen supply after birth play a part. The author observed in two of his patients temporary hypertension and trembling. These symptoms occur during disorders in or near the sympathetic centers. The author thinks that one of the factors retarding the hemolysis should perhaps be searched for in this region.

Abscess of Liver Coexistent with Cystic Disease of Pancreas. P. Huard and A. Bigot.—p. 216.

Urea and Amino Acid Nitrogen in Cardiopathies.—Two factors induced Stefanovic and Jovanovic to study the relation between the nitrogen of urea and the nitrogen of the amino acids in the blood of patients with cardiopathies. The first one is the modification of the hepatic function during cardiopathies. Under the influence of the venous stasis, the hepatic volume increases; the dilated vessels compress the hepatic cells and impair their functions. The degree of impairment depends on the duration of the cardiac compensation. If the cardiopathy is recent, the impaired hepatic function can be favorably influenced by treatment with cardiac tonics. On the other hand, if anatomic lesions of the liver result from prolonged stasis, cirrhosis develops and the impaired function can no longer be rectified. The second factor concerns the role of the liver in the protein metabolism. Under normal conditions the major portions of the amino acids carried by the portal blood are transformed by the liver into urea. Only a small portion of the amino acids passes through the liver unchanged and with the nitrogen of urea and the other nitrogen compounds of the blood forms the nonprotein nitrogen. In studies on these two factors, the authors decided to investigate the proteolytic function of the liver in patients with cardiopathies at the beginning, during and at the end of the treatment with cardiac tonics. In determining the ratio between the nitrogen of urea and the nitrogen of amino acids, they found that there is a diminution of the ratio at the beginning of the treatment; that under the influence of cardiac tonics it increases progressively and that at the end of the treatment it is normal in all cases in which there was no ureal retention, because of renal venous stasis, and in which the liver was not cirrhotic. There is a progressive augmentation of the ratio in the course of treatment and a ratio below the normal at

the end in all cases in which there is initial cardiac cirrhosis. If there exists only a temporary lesion of the kidneys at the end of the venous stasis, the ratio at the beginning is higher than normal because of the ureal retention. It returns later, under the influence of the treatment, after a phase of a pseudonormal ratio and a phase of decreased ratio, to a normal level. In patients with cardiorenal or renocardiac disorders the ratio remains, in spite of treatment, always higher than normal, because of the permanent retention of the urea. It diminishes only slightly in the course of the treatment.

Carotid Sinus Syndrome: Its Clinical Significance and Its Therapy. P. H. Rossier.—p. 531.

Irradiation of Carotid Sinus in Hypertension.—Delachaux and Schneider, on the basis of their observations, conclude that the treatment of hypertension by irradiation of the carotid sinus with short waves can be used for ambulatory treatment. They give three treatments a week for a period of from two to three weeks. They obtained improvement in fifteen of their thirty-three cases when the usual medicinal methods had failed. The best results were obtained in the patients with arteriosclerosis and essential arterial hypertension. In generalized arteriosclerosis with hypertension, however, the results were less frequent and less clear. Finally, the patients with chronic nephritis reacted only slightly to the irradiation. In essential hypertension and in arteriosclerosis the patients experience a sensation of well-being at the same time that a greater or lesser decrease takes place in their arterial tension, whereas the patients with chronic nephritis and often also those with generalized arteriosclerosis have disagreeable sensations and slight fluctuations in blood pressure. The method is contraindicated in chronic nephritis, asystole and thyroid disturbances. If generalized arteriosclerosis is accompanied by hypertension the short wave treatment of the carotid sinus can be tried, but if the reactions after the first irradiations are disagreeable it should be discontinued.

Action of Embryonal Cardiac Hormone.—Purjesz and Tószöghy point out that Miko and Törö produced from the hearts of animal embryos a hormone which exerts a specific action on the cellular-nucleus of the cardiac muscle. The hearts are obtained at an early stage of development, that is, at a time when no nervous elements have as yet developed in the heart. This cardiac hormone apparently counteracts the factor that seems responsible for the degeneration. By reestablishing normal amitosis, the hormone effects regeneration. Purjesz and Tószöghy tried this hormone on animals and later on patients. They gave the hormone simultaneously with diphtheria toxin to a group of rabbits; to another group they gave only the diphtheria toxin, and a third group of controls was left untreated. It was found that, when the animals which had been given only toxin were weak and stuporous, those which had been given also heart hormone showed almost the same behavior as the controls. The symptoms of the animals as well as the post-mortem observations indicate that the hormone is capable of preventing the lesions of the cardiac muscle which are produced by the toxin of diphtheria. The authors further tried the hormone on fifty-six patients the majority of whom had myodegeneration of the heart but some of whom had myocarditis or angina pectoris. The hormone was administered by intramuscular or subcutaneous injection in quantities of from 2 to 4 cc. daily for periods of from two to four weeks. After reporting several cases the authors say that in most cases the former complaints disappeared rapidly. Physical examination usually revealed considerable improvement, but no changes appeared in the electrocardiogram. Further, the authors administered the hormone in the form of tablets to thirty-four patients with diphtheria (mainly children). Disturbances in the cardiac

muscle developed in only two patients and these recovered. The authors reach the conclusion that the cardiac hormone is an effective therapeutic agent for myocardial disorders.

- Familial Cooley's Disease: Two Cases. D. Mircoli and O. Brunelli.—p. 309.
*Tuberculous Hilitis in Adolescents and Adults. F. Cucchini.—p. 328.

Tuberculous Hilitis.—Cucchini reports eight cases of acute tuberculous hilitis in adolescents and adults. In all cases reported by the author (as well as in those of the same condition which have been reported in the literature and are now reviewed by the author), the onset of the disease is acute and the symptoms are similar to those of typhoid. The disease develops immediately after a physical effort or after an exaggerated exposure of the patient to the sun. Symptoms showing involvement of the respiratory tract appear late in the evolution of the disease. The x-ray examination of the thorax shows the presence of a large adenopathy at the hilus of the lung. The roentgenograms show evidences of a previous hilar or perihilar tuberculous infection. The disease is either a reinfection with selective localization at the hilus or an aggravation of hilar tuberculosis. The evolution depends on whether or not it remains circumscribed (up to complete disappearance) to the hilar lymph nodes or else it involves the collateral pleura and collateral parenchyma of the lung. As a rule the disease remains at the hilar lymph nodes and has a benign evolution to recovery of the patient as the roentgenogram shows favorable modifications of the hilar enlargement. Collateral exudative pleuritis and collateral interlobar fissuritis may complicate the disease but regularly they regress after a certain long period of a benign evolution, unless parenchymal infiltrations develop simultaneously. The diagnosis is made from the character of the roentgenogram as described in association with the given clinical symptoms. In the group of patients reported by the author the disease followed a benign evolution without complications in the four patients who had treatment early in the disease. Collateral exudative pleurisy in two cases and interlobar fissuritis in one case complicated the disease, which followed a benign evolution to complete recovery of the patients in all cases but two in which infiltration of the lung parenchyma developed.

- *Influence of Vitamin C on Coagulation of Blood in Relation to Clinical Evolution and Treatment of Gingival Hemorrhages. G. Fasoli and O. Hoffer.—p. 413.
Scurvy and Pathology of Dental Apparatus in Adults. M. Nicolò.—p. 462.

Vitamin C and Coagulation of Blood.—Fasoli and Hoffer obtained satisfactory results from the administration of vitamin C in the treatment of acute hemorrhagic gingivitis. They observed the time of coagulation of the blood of ten patients who were suffering from acute hemorrhagic gingivitis and had the vitamin C treatment. The patients had a daily allowance of 0.03 or 0.04 Gm. of vitamin C, which was administered by the oral route up to complete disappearance of the inflammation and of the hemorrhage, which took place in from five to eight days. The time of coagulation of the blood was determined before and one day after administration of the first dose of vitamin C and again after completion of the treatment. The determinations of the coagulation time were made on the gingival blood. The authors found that the treatment controls the disease. The time of coagulation of the blood is almost unchanged after a clinical recovery of the patient has taken place. The authors explain the apparently conflicting results by means of the following pathogenic interpretation: A general tendency to the development of hemorrhages (observed in hemophilia and similar conditions) is in pathogenic relation with both a condition of hypo-avitaminosis C and an alteration of the time of coagulation of the blood. Local hemorrhagic conditions probably depend on disturbances of the local capillaries. The vitamin C treatment controls the general hemorrhagic tendencies by controlling hypo-avitaminosis C and by regulating the time of coagulation of the blood, whereas it controls the local hemorrhagic disorder by making normal the nutritional conditions and resistance of the capillaries without interfering with the time of coagulation of the blood.

Vitamin B₁ in Alimentary Edemas of Nurslings.—Kollmann says that beriberi, which is caused by a deficiency in vitamin B₁, occurs in two forms, one with and one without edema. In the one with edema the kidneys are not impaired but the water exchange is disturbed. Recently starvation edema as well as the nutritional edemas of nurslings have been explained as a deficiency of vitamin B₁. In view of this fact it seemed logical to use vitamin B₁ as a diuretic and the author decided to investigate to what extent the administration of vitamin B₁ would counteract alimentary edemas in nurslings. The vitamin B₁ was either administered by intramuscular injection or it was given by mouth together with the food. In case of injection the vitamin seemed to act somewhat more promptly than after oral administration. It was administered to eighteen nurslings who were less than 11 months old and all of whom had severe forms of acute or chronic nutritional disturbances, in the course of which severe edemas appeared. The medication with vitamin B₁ resulted in a rapid elimination of the edema. The author gives brief reviews of some of the case histories and says that he tried vitamin B₁ also in edematous conditions of newly born and of prematurely born infants. Here again the edemas subsided, but the action was not quite as prompt as in the first group. The author concludes that vitamin B₁ eliminates edemas in alimentary conditioned edemas of nurslings and has a stabilizing effect on hydrolability.

*Cranial Injuries. D. Kulenkampff.—p. 414.

Cranial Injuries.—For the sake of clarity in the discussion of the injuries to the brain, Kulenkampff limits himself to the terms concussion and contusion. Concussion is manifested by a brief period of loss of consciousness frequently associated with vomiting, and a headache which disappears in the course of a few hours or a few days. The lumbar puncture alone can determine whether tearing of the cerebral blood vessels has taken place. In contusion there is trauma of the brain tissue causing swelling and rise in the intracranial pressure. As a rule there is blood in the cerebrospinal fluid, the pressure of which rises with the gradual development of the reactive swelling of the brain. The rise in the pressure of the cerebrospinal fluid makes it possible in many instances to estimate the compensatory capacity as expounded by Kocher and by Cushing. Two cases are cited in which the cerebrospinal fluid pressure equaled 400. In the first case removal of 5 cc. reduced the pressure to 200, while in the second it was necessary to remove 10 cc. to bring it down to 200. The compensatory capacity in the first case was more pronounced than in the second. The anatomic structures involved in the compensatory phenomenon are the sinuses, the veins, the ventricle system of the brain and the numerous large lymph spaces on the one hand, and the development of the cranium and the constitutional type of variations of the mentioned anatomic structures on the other. For the consideration of the intracranial pressure the anatomic division of the cranial cavity into three parts is confusing; the author prefers to speak of the anterior and posterior areas of pressure. Repeated lumbar punctures are essential for the recognition of the type of injury and therapeutic indications. The fear of renewed hemorrhage as the result of lowered pressure is without foundation. The numerous symptoms resulting from cranial injuries are principally the result of inadequate regulation of the circulatory systems. This is demonstrated by the immediate

improvement in some of the cases brought about by one or two late spinal punctures. The author believes that the number of late complications could be materially lowered by continuing the original treatment to the point of restoring the patient to full working capacity.

Friedman's Test in Diagnosis of Extra-Uterine Pregnancies.—Dubrausky and Martzy report the use of Friedman's test in forty-five cases of extra-uterine pregnancy of a chronic nature, with forty positive and five negative reactions. To determine the usefulness of this test the patients were divided into three groups. In group 1 (twelve patients) reaction took place within seven days, in group 2 (fifteen patients) between seven and fourteen days and in group 3 (eighteen patients) after fourteen days. Group 1 showed a positive reaction in all cases, group 2 in fourteen and group 3 in fourteen. In order to ascertain the reason for the negative reactions the authors investigated the microscopic condition of the chorion and discovered that as long as the chorionic elements, or a great many of them, were alive and connected with the maternal organism the reactions were positive (two adverse instances). The authors also applied Friedman's test in 106 cases in which the previous history of the patient and the clinical examination invited the suspicion of an extra-uterine pregnancy. The negative reaction of the test was confirmed by the clinical developments. In four of five other cases the positive reaction of Friedman's test was also clinically corroborated. In twenty-four cases of acute pathologic conditions Friedman's test was not employed. The clinical diagnosis was followed at once by operative intervention. The authors infer that Friedman's test has no significance in acute conditions, especially as there is no time to apply it. The authors summarize their conclusions in the statements that Friedman's test has diagnostic value only in cases in which chronicity develops if a possible extra-uterine pregnancy is excluded, but even in these cases reaction may be regarded merely as one of the important diagnoses and does not dispense with the usual clinical and laboratory tests.

Icterus in Scarlet Fever.—Wisch says that, although icterus has become rare as a complication of scarlet fever, he recently observed two such cases. The first patient was a man aged 29 and the second a boy aged 8. Neither patient had previously had hepatic or biliary disturbances. In the first case, icterus and hepatic impairment appeared during the first week of the scarlet fever, apparently simultaneously with the exanthem. All symptoms of the hepatic impairment disappeared in little more than eight days. It is noteworthy that, as the icterus subsided, a typical scarlatinal rheumatoid appeared, which likewise disappeared in from seven to eight days. In the second case the icterus developed during the second week of the scarlet fever, that is, during the stage of defervescence, and was accompanied by acute dyspeptic symptoms. It is of interest that it followed a cervical lymphadenitis and that it likewise disappeared after ten days. In the first case the successive appearance of the icterus and the doubtlessly allergic rheumatoid indicated an allergic genesis of the icterus and of the causal hepatic disorder. Moreover, the rapid cure of the rather severe icterus indicated this pathogenesis in both cases. At any rate,

the benign and rapid course of the hepatic lesion and of the icterus excluded the accidental concurrence of scarlatina with infectious icterus (Weil), with a severe cholangitis or hepatitis of bacillary origin or with catarrhal icterus. In the second case the allergic character of the icterus was moreover indicated by its appearance during the nonfebrile period and immediately following a benign cervical lymphadenitis. The author concludes that the two cases of icterus during scarlet fever belong to the group of anaphylactic or allergic manifestations which are elicited by the toxin of scarlatina. It is important to know that the icterus which develops during the first to third week of scarlet fever is generally not a malignant but a benign complication, which is followed by rapid recovery.

Roentgenologic Diagnosis of Hypermaturity of Fetus.

—Stampfel and Tscherne say that hypermaturity of a fetus is frequently estimated on the basis of length and weight. However, since children born at term are occasionally abnormally large and since hypermature infants are not always of excessive size, length and weight have only a limited value in the estimation of hypermaturity. For this reason it has been suggested that the maturity of the infantile skeleton be selected as the basis of the estimation of hypermaturity. After reviewing the literature on the skeletal signs of hypermaturity the authors describe their own roentgenologic studies on ninety infants (forty-five girls and forty-five boys) who were born at term and on twenty-two who are carried beyond term. Attention was given to the existence of nuclei in the coracoid process, the upper epiphysis of the humerus, the carpus, the lower epiphysis of the femur, the upper epiphysis of the tibia and the ankle joint. The authors found that the presence of certain nuclei does not necessarily indicate hypermaturity, because the nuclei in question, such as the median humeral nucleus, the nucleus of the coracoid and the nuclei of the carpus are found also in infants who are born at term. The size of certain nuclei, however, is of considerable significance for the determination of hypermaturity; the proximal tibial nucleus and the median humeral nucleus are of great importance in this respect. A proximal tibial nucleus with a diameter of at least 7 mm. and a median humeral nucleus with a diameter of at least 5 mm. was found only in hypermature infants, so that, if these nuclei reach the aforementioned sizes, hypermaturity can be diagnosed. On x-ray exposures of fetuses who are still in utero, the authors' demonstration and the determination of the size of the proximal tibial nucleus is possible even through the abdominal walls and thus it is a valuable sign that the pregnancy has passed beyond the normal term.

Chlorination of Water in Swimming Pools.—Dold and Remy say that for the chlorination of water in swimming pools either the direct or the indirect method of chlorination is employed. In the indirect method the water is likewise mixed with chlorine gas. However, in order to remove the free hydrochloric acid which develops, the mixture is led over a layer of marble before it is added to the water in the swimming pool. In this process there is formed calcium hypochlorite, the ion of hypochlorite assuming the active role. After citing the chemical changes that take place, the authors stress that

in the indirect method of chlorination the development of free hydrochloric acid is excluded and the subsequent appearance of free chlorine is avoided. Water which is chlorinated in this manner does not have the odor of free chlorine and is practically odorless. The authors made bacteriologic tests on the water of a public swimming pool which was chlorinated by means of the indirect method. The control tests covered a period of ten months. The specimens of water were taken at a considerable distance from the fresh water intake at a depth of approximately 1 meter and at a time when the pool was used by a considerable number of persons. The bacteriologic examination proved that as regards the number of micro-organisms the water was satisfactory; 10 cc. and probably larger quantities were free from *Bacterium coli*. Chemical tests revealed that the degree of pollution was slight, in spite of the extensive use of the swimming tank. This may be partially due to the chlorination, which influences certain indicators of pollution (ammonium, nitrite), but it is probably chiefly due to the continuous intake of fresh water. Complaints about cutaneous irritation by chlorine have become less frequent since the introduction of the indirect method of chlorination. Persons with sensitive eyes still complain occasionally about irritation; however, it is difficult to determine to what extent these complaints are merely due to suggestion. Conjunctivitis due to bathing water is no longer observed.

Chemotherapy of Bacterial Infections.—Reviewing the present status of chemotherapy of bacterial infections, Domagk first takes up the chemotherapy of experimental streptococcal infections and of other experimental infections and then discusses the action mechanism. Experiments indicate that the sulfanilamides are useless in the entirely hopeless cases in which there is no longer any power of reacting, that early treatment with large doses is more effective than late treatment with small doses and that a change in the cocci is always the primary factor and the phagocytosis by leukocytes, monocytes and histocytes the secondary factor in the therapeutic action of the sulfanilamides. Domagk further discusses the anatomic factors that play a part in the chemotherapy of streptococcal infections and here again he stresses that it is advisable to give large doses for three or four days. If such medication has no effect it is useless to continue the treatment, because the micro-organisms are probably resistant to the sulfanilamide. In severe cases and particularly in those in which the micro-organisms enter tissues with slight blood content, such as tendons and joints, it is advisable to administer the sulfanilamide not only by mouth but also by injections. In the last part of his report the author discusses the secondary effects of sulfanilamide. He says that gastric disturbances can be avoided if the tablets are given after meals together with some milk or gruel. Shock is comparatively rare, even after large intravenous doses; because it is probably due to the rapid disintegration of too many cocci, the intramuscular injection should be preferred to the intravenous injection. It has been suggested that agranulocytosis might be elicited by prolonged administration of sulfanilamide; on the other hand, cases of agranulocytosis that were caused by streptococci have been known to be cured by sulfanilamide. Following remarks about the probable pathogenesis of granulocytopenia in connection with sulfanilamide, the author discusses lesions of the hepatic parenchyma. He cites evidence to the effect that the unsuitably prolonged administration of sulfanilamide is the cause of this complication. The urticarial exanthems that may develop as a rule disappear without causing serious damage.

In many cases the complications are the result of excessive dosage. Since prescriptions have been made obligatory for sulfanilamide preparations, indiscriminate use and excessive dosage will become less frequent and so will also the complications.

Cushing's Syndrome as Initial Sign in Schizophrenia.—Voss points out that incretory disorders are not exceptional among patients with schizophrenia but that endocrine syndromes (that is, not just some isolated incretory symptom) have been reported only rarely in cases of schizophrenia. He thinks that an incretory syndrome can be regarded as related to the psychosis only if its first manifestations appear at the time of the onset of the psychosis. He says that it was recently pointed out by Kehler that patients with Cushing's disease occasionally exhibit impoverishment of the emotional life and hallucinations. All of the five cases of schizophrenia described by Voss exhibited the chief symptoms of Cushing's disease, mainly the characteristic distribution of fat tissues in connection with hypertension. These symptoms are combined in the different patients with other manifestations of Cushing's syndrome; only the striae distensae were never observed. The author gives brief histories and shows photographs of the five patients; in all of them the endocrine syndrome, which always greatly resembled Cushing's disease, appeared together with the first signs of schizophrenia. Symptoms indicating the presence of a hypophysial tumor, however, were never observed. From this the author concludes that the syndrome is connected with the physical disorder underlying schizophrenia. This further supports the repeatedly observed fact that Cushing's syndrome is not necessarily pathognomonic for a basophil adenoma of the anterior lobe of the hypophysis but that other disorders may be the primary factor. It cannot be doubted that, especially in the acute cases of schizophrenia, physical disturbances play a part. In the author's cases it can be assumed that the schizophrenic process involved particularly the endocrine system and elicited the endocrine anomalies that belong to Cushing's syndrome. In all patients the incretory syndrome disappeared a short while after the psychosis became manifest, which indicates that the endocrine disorder may take a rapid course and probably is not identical with the process eliciting the schizophrenia but is only a secondary effect of this process.

Collapse Therapy of Pulmonary Tuberculosis.—Bucholdt reports the results of the collapse therapy (exclusive of thoracoplasty) of pulmonary tuberculosis in the patients who were treated at the clinic for tuberculous patients in Jena during the years from 1925 to 1935. He made his follow-up examinations in 1937, that is, from two to twelve years after the beginning of the collapse therapy. The therapeutic results in those who were still alive were estimated on the basis of the presence or absence of tubercle bacilli in the sputum. The collapse therapy was carried out in 297 cases; in seventy-six others it was not employed, although it was indicated either because the patients did not consent to it or because collapse could not be induced on account of pleural adhesions. These seventy-six cases provide a basis of comparison for the therapeutic evaluation of collapse therapy. It was found that of the patients who had

been subjected to unilateral pneumothorax 48.5 per cent were free of bacilli from two to twelve years after the collapse therapy; of those who had been subjected to bilateral pneumothorax, 21 per cent were free of bacilli. There were indications that favorable therapeutic results are to a great extent dependent on the long duration of the pneumothorax therapy. Even if the last part of the pneumothorax therapy is ambulatory, this favorable result can be realized. The therapeutic results were most favorable in the patients between 20 and 25 years of age but they were not much less so in those up to the age of 45. Unilateral pneumothorax produced freedom from bacilli in 48.5 per cent of the cases treated; in those in whom, in spite of the same indications, the pneumothorax was not induced, freedom from bacilli was obtained in only 21 per cent. Thus if in a group of patients with pulmonary tuberculosis 100 are cured spontaneously, 230 could be cured by collapse therapy.

*Combined Medical and Surgical Treatment of Mercury Bichloride Poisoning. N. G. Sadkina.—p. 77.

Mercury Bichloride Poisoning.—Sadkina reports twenty-four cases of mercury bichloride poisoning treated by bilateral decapsulation of the kidneys and a cecostomy. The theories advanced to explain the beneficial effect of decapsulation of the kidneys are (1) formation of vascular channels between the denuded kidney and the surrounding tissue, (2) lowering of the intrarenal tension and (3) effect of removal of sympathetic fibers on the vascular spasm with the resulting improvement in the nutritive and the functional state of the kidney. The earlier the decapsulation, the greater the chance of preventing the aneuria or of shortening its duration after it has developed. Experience at Sklifasovsky Institute suggests that the operation is indicated within the first six hours after poisoning. The rationale of cecostomy is to be seen in the fact that ingested mercury is eliminated principally by the kidneys and by the large intestine. A cecostomy opening is utilized to remove the drug by continued flushing with a weak solution of potassium permanganate. Azotemia increased as a rule during the first days, the urea blood content rising as high as 560 mg. This was always accompanied by a fall in blood chlorides, a diminution in alkali reserve (from 15.7 to 27.7 per cent of carbon dioxide) and manifestations of acute acidosis. The clinical picture of patients treated by decapsulation was milder than that of patients who took a similar dose of the drug but were not subjected to decapsulation. The four fatalities among the patients who were subjected to decapsulation were probably due to a late operation or a weakened organism prior to poisoning. The author concludes that decapsulation and a cecostomy is the method of choice in the treatment of mercury bichloride poisoning. The operation is best performed under spinal anesthesia and at the earliest possible moment. Immediate lavage of the stomach and in the later stages infusion of hypertonic solution of dextrose and of large amounts of 5 per cent sodium bicarbonate are to be employed in a routine manner.

Acute Venous Stasis in One Arm. J. L. A. Peutz.—p. 2236.

Acute Hematogenic Osteomyelitis.—At Nierstrasz's clinic in Groningen, the treatment of acute osteomyelitis was usually limited to incision of the subperiosteal abscess. He reviews a material of 143 cases of acute hematogenous osteomyelitis which were treated at his clinic in the course of the last ten years. This review reveals the advantages of the conservative treatment during the acute stage. The author classifies as

acute all cases in which the patients had not been ill more than three weeks before hospitalization. Statistical and clinical evidence as well as theoretical considerations prove that the incision of the subperiosteal abscess is the best method of treatment and far superior to trepanation of the bone marrow with trephine and chisel. The mortality rate in the author's material was 17.4 per cent. In remarks about the prognosis he says that it is unfavorable in the cases in which the temperature is around 40 C. (104 F.) before the operation; in those in which it is less than 39 C. (102.2 F.) it is comparatively favorable. In children and particularly in nurslings the prognosis is much less favorable than in patients of the puberal age.

Vacation Camps for Children and Tuberculosis.—Schmitz and Bos stress the necessity of thorough examination of children who are to be sent to vacation camps. In the course of such examinations it was discovered that among them there were a considerable number who coughed. In some of these the general condition was unfavorable and it was decided to search for tuberculosis. Acute tuberculous pulmonary infiltrates were discovered in several and it was now decided that all children should be examined for the possible existence of active tuberculosis. During the three years from July 1935 to July 1938, 4,476 children who were registered for vacation camps were examined with the Pirquet test. Approximately 18 per cent gave positive reactions. These were then subjected to x-ray examination and in twenty-two of them an active tuberculous process was detected in the lungs. Thus approximately 0.5 per cent of the total number of children (4,476) had an active form of tuberculosis. In the majority of these children it had not been known that tuberculosis existed.

Treatment of Postoperative Tetany. E. Åkerberg.—p. 413.
Dystrophy of Ureteral Orifices. K. Johanning.—p. 439.

Fluid Treatment of Pyloric Stenosis.—Clausen and Ringsted investigated in six cases of pyloric obstruction the chlorine metabolism and the renal function during the dehydrated state, during the preoperative treatment with saline solution and, as far as possible, during the postoperative period. They found that dehydration and loss of chlorine may reach extremely severe degrees in cases of pyloric obstruction. In some cases dehydration and chloropenia may cause a lowering of the renal function. For the complete restoration of the normal water content it is often necessary to administer considerable quantities of sodium chloride. In some instances more than 10 liters of saline solution is needed. The isolated examination of either the diuresis, the chlorine content of the serum or the urine provides no safe criterion of the state of hydration. Determination of the chlorine balance is likewise unsuitable for the estimation of rehydration, because the intake and the elimination do not tally at the time when rehydration has been established. The authors found that the simultaneous determination of the chlorine concentration in the serum and of the chlorine concentration of the twenty-four hour urine afforded the best indication of the degree of rehydration of the body. In patients who, as the result of prolonged pyloric obstruction, have become greatly undernourished and dehydrated, these determinations must be supplemented with analyses of the plasma protein before rehydration with saline solution, in order to prevent the risk of development of a hypoproteinemic edema.

In patients with hypoproteinemia, transfusion of blood, if necessary several times, must be resorted to during the preoperative period in order to raise the serum protein concentration and thus make rehydration possible. The preoperative treatment with saline solution, if possible, should be supplemented by the administration of dextrose, at any rate during the last days preceding the operation. Isotonic solution of dextrose should be given after the operation to compensate for the total physiologic loss of fluid, and isotonic saline solution should be given after operation to replace the nonphysiologic losses of fluid and to continue rehydration, if the patient has not been rehydrated before the operation.

*Erythroplasia. E. Poppe.—p. 1326.
Prontosil Intoxication. K. Motzfeldt.—p. 1327.

Erythroplasia.—Poppe reports a case of erythroplasia on the dorsal side of the glans penis and the adjacent part of the prepuce treated by radium in a prosthesis. One and a half years after discharge there was no sign of recurrence. He says that erythroplasia so called by Queyrat to designate the color of the efflorescence, the infiltrations of the tissue and the likeness to leukoplakia, although the latter does not show malignant degeneration with the same regularity, is a rare form of precancerous disorder. The clinical picture is characteristic enough so that diagnosis should not be difficult if the disease is known. If erythroplasia is suspected, a biopsy is called for. From the start erythroplasia should be treated as cancer, since cases not treated radically show malignant proliferation with formation of metastasizing spinocellular carcinomas.

- *Investigations on Effect of Sulfanilamide in Erysipelas (200 Cases Treated). B. C. Christensen.—p. 1379.

Effect of Sulfanilamide on Erysipelas.—Christensen compares the 200 cases of erysipelas from Blegdam Hospital from July 1937 through 1938, all treated with sulfanilamide, with the series of 100 cases, identical on admission, from the period just before the introduction of the chemotherapy of this disease. In the cases treated with sulfanilamide the febrile period was reduced several days. While no safe conclusion can be drawn, he says, as to the effect of sulfanilamide on the complications in erysipelas, abscess of the eyelid occurred only once in the 200 treated cases, five times in the 100 cases. The death rate in the cases treated with the drug was 1 per cent, in the other cases 9 per cent. The dosage used was from 0.9 to 2.7 Gm. daily for from three to five successive days.

PROBLEMS IN SPECIAL STUDY FOR GENERAL PHYSICIANS

CHAIRMAN'S ADDRESS

S. JUDD BEACH, M.D.

PORTLAND, MAINE

The sore spot in graduate ophthalmologic teaching still seems to be the inadequate provision for training the general practitioner who is undertaking to become a specialist. One example will present the situation. Take the case of one physician for ten years in general practice. He then spent six months taking special courses at a mediocre eye and ear hospital. Although he had some doubts as to the quality of the instruction he had received, he emerged to specialize in ophthalmology and otolaryngology. Several years of experience have now increased his misgivings as to his qualifications. At present he wishes the certificate of the American Board of Ophthalmology but is more than simply dubious about his fitness to take the examinations. Yet by this time his hospital service and personal responsibilities preclude his taking time out for consecutive formal study. Members of the examining board who conducted conferences with possible candidates at recent instructional courses remarked on the frequency with which they were faced with variants of this problem and how little could be done about it.

Two rather distinct sorts of postgraduate instruction are now provided in our specialty. Neither entirely meets the needs of these men. The approved training for those who can get it is the complete integrated course. At its best it correlates formal study and didactic lectures with the clinical experience of a residence. It is designed to take the novice and after one or more years turn him out ready to undertake special practice.

In contrast to this there are what have been called "extension courses." These are usually one or two hours of rather elementary and often informal demonstrations. The time limitation holds such conferences to a restricted field. Their greatest value has probably been to bring to practitioners the newer points of view and discoveries. This sort of instruction has been made widely available by the various state medical societies with the encouragement and advice of the Council on Medical Education and Hospitals of the American Medical Association. They arrange short intensive brush-up courses in various community centers. Louisiana, for instance, is now bringing them to each councilor district. Two general methods have been followed, differing chiefly in arrangement. In the two methods the

instruction is essentially the same. In one, the courses are given consecutively in the same place for a period lasting from a few days to a fortnight. Then the same instruction is repeated in some other locality. The other plan is the so-called circuit method. With this arrangement the first lecture, often with movies and clinics, is repeated in a different place every day for a week, moving around a circuit of perhaps five centers. During another week the second demonstration follows the same circuit. The entire series may require as much as ten such weeks.

THE EXAMINING BOARD

For work in perfecting both the thorough courses and the short conferences, a debt is owed ophthalmologists that has been largely forgotten. Both types of instruction were developed under leadership in which the guests of honor of this section for the past two years were conspicuous. Dr. Edward Jackson and Dr. John E. Weeks, to whom last year's transactions were dedicated, and our two present guests, Dr. Lancaster and Dr. Greenwood, exerted a potent influence over the early progress of American postgraduate medical training. In large part this was through agency of the American Board of Ophthalmology, of which they were original or early members. Admittedly the necessity of preparing applicants to meet the requirements of the board has compelled teaching institutions to undertake more adequate instruction. Departments of graduate education in state universities and medical societies are frank in claiming that their courses, as one of them puts it, "are adaptable to the requirements of the specialty boards." Yet it should not be forgotten that this process started and had gained considerable headway during those ten uneasy years after our board was functioning preceding the organization of the next specialty board by the otolaryngologists. It was largely the resulting improvement of educational methods in ophthalmology during this critical decade of solitary effort by the ophthalmic board that persuaded our sister specialties to adopt the examining board system. There are now twelve such boards coordinated in the Advisory Board of Medical Specialties.

It might almost be taken as an omen that the American Board for Ophthalmic Examinations, as it was first called, was born in a rousing storm. The original appointees were Miles Standish, Alexander Duane and William H. Wilder from the American Ophthalmological Society; Wendell Reber, Walter B. Lancaster and Frank C. Todd of the American Academy of Ophthalmology and Otolaryngology, and Edward Jackson, Hiram Woods and E. C. Ellett, representing this section. Woods and Reber were meeting in Boston with Dr. Lancaster as the committee on organization when a tempest blew the skylight off the Lancaster residence

and later stalled the train on which Dr. Woods was returning to New York. The great tragedy was the loss of Dr. Reber. Worn out with his arduous labors he was seized with pneumonia in Memphis, where the first examination was held, and succumbed at the home of relatives in St. Louis. His well known generosity to his younger colleagues especially fitted him for service on a board organized chiefly to stimulate them to sounder scholarship. He was a man of international reputation and the year before his death had been a member of the council of the Oxford Congress.

Conceived in these trials, no stepchild could have been less welcome than this devoted board. Ophthalmologists as a group seem always to have been hardy nonconformists and they resented the slightest suggestion of what the columnists like to call regimentation. Many educators in particular felt the implied reflection on their methods and had no relish for the often difficult matter of revising their instruction. Then there were those who regarded the examination as an affront. This attitude has not yet entirely died out but it is less open because applicants are more conscious now that by showing it they invite suspicion of their ability to pass. Such a pose was made ridiculous at the outset by the insistence of Dr. Edward Jackson, while a member of the board, that he be examined before receiving the certificate. Legend hints that his colleagues approached with considerable hesitation the ordeal of giving this examination. Evidence of lack of sympathy with the activities of the board may be discerned in the minutes of its meetings. It was hoped, for instance, that the appointing societies would make appropriations to defray the expenses of organization. Quite definitely no funds were forthcoming, so that the original members not only gave their time but even paid their own transportation to the places of examination.

THE WORLD WAR

The trials of the board were immediately increased by the outbreak of the World War. The war had a somewhat mixed effect on the progress of graduate ophthalmologic education. It may have delayed the recognition of the importance of optics and visual physiology as a part of the curriculum. Of the many contributions to education of our guest of honor, Dr. Walter B. Lancaster, none is more peculiarly his than finally to have gained proper recognition for this subject. Not less than twenty years before it was segregated by the American Board of Ophthalmology as a separate part of the examination, Dr. Lancaster had read a paper before one of the major meetings on the role of physiologic optics in the training of ophthalmologists. Just what he said will never be known, as the subject was not at that time regarded as worthy of a place in the transactions. Probably the paper was not far different from the one in the records of this section for 1913. In it Dr. Lancaster calls to attention how visual physiology underlies most clinical procedures in ophthalmology and cites examples covering a multitude of fields, from refraction to lacrimal disorders. The board, however, was not yet ready to make it a coordinate subject. Dr. Lancaster was then commissioned as chief of the department of ophthalmology at Camp Devens and later was in charge of the research laboratory in aviation at Mitchel Field. It was not until his return to the board in 1932 that as part of a sweeping revision of the method of examination by the board he established optics and visual physiology as a definite division of the examination. As an immediate consequence, many

schools and hospitals have already installed laboratories in this subject and established courses of varying degrees of excellence.

The war gave to our other guest of honor, Dr. Allen Greenwood, an experience which led to the establishment of thorough didactic training for residents and the inauguration of the now popular short conferences. After serving in the British army in 1915 as an ophthalmologist with the Harvard Unit, he became senior consultant in ophthalmology for the American Expeditionary Forces. It therefore fell to him to arrange for the instruction of ophthalmologists of varying attainments serving with the troops. He planned courses to be given by Dr. Lister at Boulogne and formulated the orders to the Surgeon General's Office under which Dr. Lee M. Francis proceeded to Paris to supervise the instruction for ophthalmologists. This experience inspired Dr. Greenwood to obtain for residents at the Massachusetts Eye and Ear Infirmary a course of formal instruction in relation to cases observed in the wards. This course did much to give the infirmary its early and lasting distinction as a teaching hospital.

The success of the intensive courses in the army also suggested to him the possibility of instituting something similar in connection with meetings of the American Academy of Ophthalmology and Otolaryngology, of which he had been president in 1918. Absence on foreign service had prevented his occupying the office. Holding it, however, made him for three years a member of the council. Printing of the minutes of the academy had just begun during the secretaryship of Dr. Luther C. Peter, later chairman of the examining board. They intimate that Dr. Greenwood tried in 1919 to induce the council to inaugurate this sort of instruction. Though the plan had also been suggested by Dr. Secord H. Large, the treasurer, and although there is also note of a demonstration of pathologic slides by Dr. William C. Finoff for Dr. Jackson's committee of graduate education, it was a year before the council could bring about the instructional lectures. At the end of the session of 1920 Dr. Greenwood was able to report that Dr. Peter and probably Dr. George E. de Schweinitz would undertake them during the closing days of the Philadelphia session the next year. The necessity of recuperating from the severity of his foreign service prevented Dr. Greenwood from accepting the chairmanship of the committee appointed to organize these courses. The arrangements were therefore turned over to a committee headed by Dr. Harry S. Gradle, who had also advocated the plan. The success with which they developed this venture is a matter of record. It has served as a model for the multitude of short courses in use by other societies and by other general and special groups. Those who underwent the sketchy teaching before the advent of the board are rather dazzled by the present fellowships in ophthalmology lasting from three to five years. Instructional sessions with 100 or 200 communicants contrast with the days when the best training that could be hoped for was to be exposed to ophthalmology as an intern. The vaccination usually took, in spite of the lack of formal teaching, but if it did not that was no one's concern. The haphazard teaching of the time was characterized in 1914 by Dr. Frank C. Todd. He was the first secretary of the examining board and the second member to be lost. He had been head of the department of ophthalmology at the University of Minnesota Medical School, where one of the very early courses leading to a degree in ophthalmology was conducted. His death

from pneumonia followed a distinguished army service. Thereupon Dr. William H. Wilder, for so many years the guiding spirit of the board, succeeded to the secretaryship. "We have only short courses," Todd had said, "and one desiring to take up practice has no standard set for him." Now this exactly describes the plight today of the men who are unable to obtain or take time for formal consecutive instruction. These men are not always indifferent. We have not at present enough

Fig. 1.—Location of hospitals approved for internships by the American Medical Association in 1938.

opportunities for them. Look at the list of hospitals approved by the American Medical Association for teaching interns in ophthalmology and otolaryngology. Not only are they both "few and far between," but they are so placed as to be totally inaccessible to many who need them most. The same things are hardly less true of competent graduate courses.

Is it then surprising that students try to make brush-up courses do the work of sound study? Much of the criticism of these short courses, and there is no little adverse comment, seems to arise from such attempts to make them take the place of solid training on the part of men who have no other resource. One purpose of these courses should be to stimulate the physician to continue his studies at home. So that if we could provide satisfactory facilities for home study it should help this situation. These men represent the immovable mountain to which we have to bring the prophet. Two possibilities have been discussed by members of the examining board. One is to make wider use of the "long, short course." This kind of instruction is now well established. All that it needs is broader distribution. Sometimes designated as "progressive courses," they consist of a series of demonstrations taking from three or four days to a fortnight. They are patterned after the outstanding one in ophthalmic pathology conducted annually by the American Academy of Ophthalmology and Otolaryngology. At various other instructional sessions, different subjects have been handled in the same way with equal success. Courses in orthoptics and in practical surgery are regularly oversubscribed. Such is the demand that it looks as though this method would ultimately expand to include the remaining subjects and, if given reasonable encouragement, rapidly bring them to the less favored localities.

FORMIDABLE MEDICAL TEXTBOOKS

The other suggestion is much more complicated. That is to introduce the extension course in the accepted sense. For example, can home study courses like those

in ophthalmology arranged by Dr. Gradle to be offered through the American Academy of Ophthalmology and Otolaryngology for use of residents be adapted to men who have failed to obtain hospital appointments? Certainly they need them most. Two complications conspire to make this project formidable. The first is the nature of our literature. Most of our textbooks are not suited for home study. It is not that they are too profound but that the arrangement is rather that of works of reference than that of manuals for practice. One fault was discussed twenty years ago by Dr. Clarence Loeb of this city. He complained that you have to know what a disease is before you can look it up. He objected to the grouping according to the part of the eye involved. "There is no clinical or pathological resemblance," he said, "between iritis, sarcoma of the iris, and coloboma of the iris. In practice, iritis would be much more liable to confusion with glaucoma." He advocated teaching the method which he said clinicians use in actual diagnosis. That is to compare all conditions having the same appearance. Taking as an example circumcorneal injection, one symptom of acute iritis, he tries to name the disorders in which it occurs. First he lists the ones that spring at once to mind; then those, three times as many, that can be recollected after deliberation.

Without following this theory too literally could we devise a compromise. Suppose the Kurzes Handbuch of seven volumes could be crossed with one of the popular self-playing bridge systems. At least we might expect something more practical than books that describe every possible procedure without recommending any choice to the bewildered student. Conventional textbooks are perplexing enough to residents in a hospital who can take their difficulties to some member of the staff. To a man miles from the nearest consultant and still farther from a medical library they may be almost useless. This situation is not peculiar to ophthalmology or even to medicine. How many books genuinely adapted to home study are to be found in business administration or in social service? In many instances,

Causes of Circumcorneal Injection

Disorders suggested immediately by circumcorneal injection:	Descemetitis
Iritis	Staphylococcal cornea
Iridocyclitis	Episcleritis
Interstitial keratitis	Scleritis
Corneal ulcer	Staphylococcal sclera
Glaucoma	Burn cornea
Phlyctenular keratitis	Abrasion cornea
Other conditions for differential diagnosis:	Wound cornea
Foreign body cornea	Wound sclera
Superficial punctate keratitis	Rupture sclera
Keratitis profunda	Tumor iris
	Iridodiolysis
	Trauma coloboma iris
	Traumatic aniridia
	Panophthalmitis
	Symptomatic ophthalmia
	Traumatic cataract

lay institutions experienced in extension courses have compiled an entirely new literature to replace or elucidate the regular textbooks of the intramural courses.

To write for teaching by mail requires special gifts. The style would have to approximate the best of our instructional courses. To rewrite our literature for self instruction would take time. Under present conditions it is a wise decision of the sponsors of the home study courses to see first how they work for residents. Yet, in any case, practical manuals like the little one compiled for the army by Dr. Greenwood would be a boon to students. The large sale of stenotyped reports iniro-

duced by Dr. W. T. Davis at the George Washington University courses is indicative of the demand for instruction of this character.

ACHIEVEMENT TESTS

The other difficulty is the matter of examinations. These are a vital part of extension teaching. Even in examinations by the American Board of Ophthalmology, the function of revealing to the student his weak points and helping him to remedy them has turned out to be of no less importance than the primary one of identifying the competent ophthalmologists. Lack of tests is one of the weaknesses of all short courses. So, both for home study and for the "progressive" demonstrations, examinations are essential. Yet to test a student's knowledge in a field of this magnitude by conventional examination questions is a superhuman task. It means having the examiner read entire essays on such minutiae as provocative tests for glaucoma or the use of cross cylinders. Multiply this by the number of men to be reached and the product sounds like federal spending.

For large scale examining, some such method is needed as that used by laymen in the so-called achievement tests. This has been copied by several of the other specialty boards and was used by the American Board of Ophthalmology this year in resuming the written examination.

It is to ask questions that can be answered by choosing the correct statements from several, some of which are false; or questions that can be answered by one word, as yes or no; or by some qualification like the name of a color or by a numeral, like a measurement; or by a diagram. Most of these can be rated by clerks without special training.

As with the textbooks, the labor of preparing examinations of this sort would not be wasted even if the "correspondence courses" should be disappointing.

1. Indicate on this diagram the distance from the corneal limbus of the insertions of the four rectus muscles:

2. Transpose:
-2.00 +3.75 x 20
- .50 + .75 x160

3. The following structures are derived from the ectoderm (ENCIRCLE CORRECT STATEMENTS):

Ganglion cells,
Choroidea, Short
ciliary nerves,
Lamina cribrosa,
Corneal epithelium,
Descemet's mem-
brane, Central
retinal artery,
Pigment layers iris,
Inclusion bodies,
External rectus
muscle.

Fig. 2.—Tests for rapid rating.

There is already a demand for old examination questions of the board from candidates wishing to use them for review.

SELF-TEACHING TEXTBOOKS

Another solvent which suggests itself has the double virtue of combining in one volume the manual and the examination. It is the familiar self-teaching textbook. In other fields such books are provided with review questions for which correct answers are furnished. They differ widely in arrangement. The general principle, however, has a recognized place in home study.

SUMMARY

In short, largely by the influence of the American Board of Ophthalmology, training methods for ophthal-

mologists have been raised to a high degree of excellence. The number of opportunities is, however, totally inadequate. Poorest provision is made for the general practitioners who for whatever reason find themselves in ophthalmologic practice without adequate formal training. For these "forgotten men" four expedients have been discussed by those interested:

1. Extend the "long short courses" to include the remaining branches; equip them with appropriate facilities such as moving pictures and clinics; distribute them in the less favored areas.
2. Devise a literature for self teaching, suited to home study either with or without courses like those now being arranged for residents.
3. Provide suitable tests for checking progress made by students of both these methods, adapted like the familiar achievement tests for self-correcting or rating by clerks.
4. Combine these in manuals patterned after the familiar self-teaching textbooks equipped with review questions and furnished with correct answers.

704 Congress Street.

ALLERGY OF THE UPPER RESPIRATORY TRACT IN INFANCY AND CHILDHOOD

GEORGE PINESS, M.D.

AND

HYMAN MILLER, M.D.

LOS ANGELES

In 1925 at the seventy-sixth annual session of the American Medical Association and before the Section on Laryngology, Otology and Rhinology we had occasion to present a paper entitled "Allergy: A Nonsurgical Disease of the Nose and Throat."¹ Now, fourteen years later, we find ourselves impelled to discuss the same topic. Obviously, in the long interval since, we have not been favorably impressed with the reaction to our previous effort; we still feel it necessary to reiterate that allergy is a nonsurgical disease of the nose and throat. Specifically, we still see too many children who have been treated for repeated "colds," chronic sinusitis, chronic bronchitis and recurrent pneumonia, by "cold shots," sinus drainage and adenotonsillectomy until a frank, unmistakable attack of bronchial asthma brings a surprised awakening to the fact that the essential cause of the "colds," sinusitis, bronchitis and pneumonia is allergy. From continued experiences of this sort we are forced to conclude that there has been no marked change in the traditional belief that infection is the chief if not the only cause of all the disturbances we have enumerated and surgical treatment the chief if not the only method of therapy. We are further confirmed in this conclusion by the persistent high incidence of tonsillectomy for the relief of these disturbances, for tonsillectomy in the light of present knowledge can be justified only on the basis of a belief in the infectious nature of the process which the removal of tonsils will relieve.

In 1925 a survey of 840 allergic persons, mainly children, showed that the tonsils had been removed in 340, or 40 per cent. In 1938 a similar survey of 2,230

From the Allergy Clinic, Los Angeles Children's Hospital.
Read before the joint meeting of the Section on Laryngology, Otology and Rhinology and the Section on Pediatrics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.
1. Piness, George, and Miller, Hyman: Allergy: A Nonsurgical Disease of the Nose and Throat, J. A. M. A. 85: 339 (Aug. 1) 1925.

allergic children showed that in 751, or 33 per cent, the tonsils had been removed. Allowing for the difference in the age groups surveyed, the passing of fourteen years has not changed the incidence of tonsillectomy. In the accompanying table is presented confirmation of this incidence by other writers. In four groups of allergic patients examined respectively by Cunningham,² Hansel,³ Clarke and Rogers⁴ and Waldbott, Ascher and Giese,⁵ totaling 2,186 patients, the average incidence was 38 per cent. This ratio does not differ from that found in the population at large, for the statistical studies of Cunningham² on 7,958 college women between the ages of 15 and 19 showed that the tonsils had been removed in 2,756, or 34.6 per cent. Since the incidence is the same for the allergic group and for the general population, we are inclined to believe that the same motive inspired the removal of tonsils in the two groups, that is, to remove a source of infection. Apparently, then, it is still a common belief that the signs and symptoms of allergy are due to infection or, as an alternative, that it is still common to mistake the signs and symptoms of allergy for those of infection.

Turning first to further proof of the statement that it is still a common belief that the signs and symptoms of allergy are due to infection and using tonsillectomy as a gage of the prevalence of this belief, we asked the parents of 273 children suffering from obvious bronchial asthma whether tonsillectomy had been advised for the relief of asthmatic symptoms. Of these 119, or 43 per cent, answered that tonsillectomy had been advised definitely for the relief of asthma. Even if we should depart from our position that the only logical and justifiable basis for recommending tonsillectomy is the belief that a source of infection is being removed and thereby acquit all who recommend tonsillectomy for the relief of asthma of the belief that allergic symptoms are due to infection, we are still faced with the difficult question why tonsillectomy is so often recommended for the alleviation of asthma.

An obvious answer to this question would be that tonsillectomy so frequently alleviates asthma that the procedure is still justified by experience. Of this we have found no proof. On the contrary, the 751 children who came to the allergy clinic after tonsillectomy are evidence of the fact that the procedure frequently fails to give relief. Moreover, of 685 allergic children from whom the information was available 116, or 17 per cent, exhibited their first frank allergic symptoms after tonsillectomy and many others complained that mild symptoms had been aggravated. The failure of tonsillectomy to influence favorably the course of allergy is confirmed by Bullen,⁶ who found that in 1,000 children whose tonsils had been removed ten years previously the incidence of allergic symptoms was 4.1 per cent and that in a comparable group whose tonsils had not been removed the incidence was 3.6 per cent, or 0.5 per cent less, on which he commented "Patients who are promised relief or protection from atopy by tonsillectomy are most certainly destined to be disappointed." Cunningham,² examining 12,530 women at the University of

California, found that in those whose tonsils had been removed the incidence of asthma was 5.60 per cent and of hay fever 23.54 per cent, while in those whose tonsils had not been removed the incidence of asthma was 5.03 per cent and of hay fever 26.43 per cent. Experience therefore does not justify the removal of tonsils for the relief of allergic symptoms, whether or not the belief is held that allergic symptoms are due to infection.

One returns then to proof of the alternative, that tonsillectomy is so often recommended for the relief of the symptoms of allergy because it is still common to mistake them for the symptoms of infection. This may be the result of failure to recognize and distinguish between the atypical symptoms of uncomplicated allergy, the symptoms of allergy complicated by infection and the symptoms of infection alone and of failure to recognize and distinguish between the pathology of pure allergy, the pathology of allergy obscured by infection and the pathology of infection.

Allergy of the respiratory tract may go undiagnosed because the characteristic symptoms of hay fever or asthma are not present. Yet allergy alone may produce chronic nasal obstruction without sneezing and having little to do with enlarged adenoids and may produce frequent bouts of rhinorrhea and nasal obstruction having little to do with infection although frequently

Incidence of Tonsillectomy in Various Groups of Allergic Patients

dubbed "frequent colds" or sinusitis. Allergy alone may produce persistent sore throat unrelated to tonsillitis and "stuffy" ears unrelated to pharyngitis. Allergy alone may produce a chronic or intermittent cough without infection of the bronchi and without wheezing or dyspnea and may produce recurrent allergic bronchopneumonia with fever, leukocytosis and tachypnea without wheezing and without pneumococci.⁷ In other words allergy may simulate many of the symptoms and signs of acute or chronic infection of the respiratory tract.

There is less reason for failing to recognize allergic pathologic changes in the nose and throat than there is for failing to recognize allergic symptoms. "Cloudy" sinuses, as Proetz⁸ has shown, may be due to allergic swelling or polypoid degeneration of the mucous membrane. Polypoid degeneration, according to Kern and Schenck,⁹ is almost invariably due to allergy. The largest of chronically enlarged tonsils are also due to allergy, and a regrowth of lymphoid tissue in the tonsillar fossae after tonsillectomy is as characteristic of allergy as the original enlarged tonsils, whose size alone so often seems to be the only indication which led

to their removal. Lymphoid hyperplasia is one of the distinctive features of allergy. In ninety-five allergic children examined the otolaryngologist noted enlarged tonsils in seventy-nine, or 83 per cent. On reexamining 544 allergic children in whom the tonsils had been removed, he found an excessive regrowth of lymphoid tissue in the tonsillar fossae in seventy-one, or 13 per cent, at times within two months after removal of the tonsils. In six this regrowth had provided sufficient tissue for a second tonsillectomy, a story which in itself is often a valuable hint that the patient is allergic.

The pathologic changes of allergy may, by interfering with drainage, permit the implantation of a secondary chronic infection in the upper respiratory tract. "Secondary" is used advisedly, for when allergy and infection coexist in the upper respiratory tract allergy usually precedes infection. The allergic process often goes unrecognized because it may be modified or masked by the superimposed infection, just as allergic eczema may be modified or masked by a superimposed infection. This was clearly demonstrated by Semenov¹⁰ in his histopathologic analysis of the mucous membranes of the nose and sinuses of 500 patients with nasal sinusitis. His data show that 17 per cent of the patients examined had "manifest" allergy and 35.4 per cent "equivocal" allergy, that is allergy probably modified by infection. There was a total probable incidence of 52.4 per cent of allergic mucous membranes in the 500 examined.

In 1912 Todd¹¹ wrote:

During each attack of hay fever, swelling of the turbinates takes place causing defective drainage, secretion occurs, infection is added thereto and we have present ethmoiditis and sometimes pansinusitis. Repeated attacks may result in a persistent lesion and thus the patient may develop chronic ethmoiditis, sphenoiditis, frontal sinusitis or pansinusitis often accompanied by persistent swelling of the turbinates and especially of the middle turbinate.

This we quoted in 1925 and this in essence is still the sequence of events which we conceive to be essentially true. Basing our opinion on this conception we feel that, once infection has taken place, treatment directed solely at the underlying allergy or solely at the accompanying infection will not accomplish its purpose. Treatment of underlying allergy is often necessary to establish drainage even after extensive surgical removal of tissue, for such increased space as surgical intervention provides may be rapidly filled by the continued swelling of the allergic mucous membrane. Although treatment of the allergic process may aid the healing of accompanying infection, treatment of the infection alone can never clear up the underlying allergy.

It is evident then that the identification of allergy of the upper respiratory tract is the first essential in its proper treatment and in the prophylaxis against the complications of both allergy and infection. There is no way to estimate the ability to identify allergy of the respiratory tract in childhood by the practitioners at whose doors the responsibility lies. From what has gone before, however, there can be but little justification for recommending tonsillectomy in the presence of allergy. Thus the extent to which tonsillectomy is recommended measures either the degree to which the allergic nature of the process goes unrecognized or, if recognized, the degree to which practitioners are ridden by the tonsillectomy complex. It is therefore pertinent

to determine if possible the degree of responsibility for recommending tonsillectomy in the presence of allergy in the groups of practitioners chiefly involved, namely the general practitioners, the pediatricians and the otolaryngologists. Eighty-four patients were asked who had advised them to have their tonsils removed for the relief of allergic symptoms. It was found that nineteen, or 22 per cent, were so advised by a general practitioner, twenty-seven, or 32 per cent by a pediatrician and thirty-eight, or 45 per cent, by an otolaryngologist. The conclusion is obvious that the responsibility for advising tonsillectomy for the relief of allergic symptoms may justly be distributed in like proportions.

Although our thesis is that allergy is a nonsurgical disease and that therefore tonsillectomy should not so frequently be resorted to for the relief of its symptoms, we must not lose sight of the possibility that allergy is involved only incidentally in what may be termed the "tonsillectomy epidemic." Despite the statement of Cunningham² that "there is a growing tendency to question the value of tonsillectomy as a prophylaxis against infectious diseases and as a preventive measure or cure for such systemic diseases as rheumatism, chorea and carditis," of McLean¹² that there is no significant diminution in the number of colds after tonsillectomy, of Kaiser¹³ that bronchitis is twice as common after tonsillectomy, of Dean¹⁴ that he finds it impossible to say that any tonsil is the seat of chronic infection except after removal and microscopic study and of Cernack¹⁵ that "simple hypertrophy is not an indication for tonsillectomy," there are, according to a recent survey of Collins,¹⁶ 1,235,000 tonsillectomies a year in the United States in the age group under 15 years. This can be explained only in the words of Glover,¹⁷ commenting on the 200,000 annual tonsillectomies performed in England:

It is a little difficult to believe that among the mass of tonsillectomies performed today all subjects for operation are selected with true discrimination and one cannot avoid the conclusion that there is a tendency for the operation to be performed as a routine prophylactic ritual for no particular reason and with no particular result.

To this Layton,¹⁸ another English physician, somewhat less dispassionately added "Enlarged tonsils should be removed from the terminology" not the pharynx." In the United States Cunningham,² Dean,¹⁴ Forsythe¹⁹ and Kaiser¹³ lend assent. It may well be then that allergy has only incidentally been caught in the wave of tonsillectomies, so that the persistence of this procedure in the treatment of allergic symptoms is not entirely due to the fact that allergy is unrecognized or ascribed to an infection cause. Yet, since tonsillectomy undoubtedly arose from the concept of removing a focus of infection, it is not amiss to state dogmatically that the pathologic disturbances of the anatomy and physiology of the respiratory tract by

allergy are mediated by a recognizably different process than those of infection. The importance of recognizing the allergic process is threefold: 1. A correct diagnosis increases the probability of giving relief and decreases the probability of misdirected treatment. 2. It prevents development of more serious allergic disturbances. 3. It prevents secondary infection with the probability that such infection will be difficult to control because the accompanying allergy is not recognized. Inherent in the early recognition of allergic symptoms is the promise that the allergic child will then be protected from the characteristic physical disabilities and handicaps which result in mental, social and economic maladjustment. In conclusion, may we say that we decry the evidence which leads us to believe that there has been an unjustifiable lag in the application of our knowledge of allergy and that fourteen years from today we hope we shall not again feel impelled to call attention to the responsibility of the general practitioner, the pediatrician and the otolaryngologist in applying this knowledge.

672 South Westlake Avenue.

ABSTRACT OF DISCUSSION

DR. FRANCIS M. POTTENGER JR., Monrovia, Calif.: This paper is timely and, although approached from an entirely different angle, augments the statements that were made by Drs. Reimann and Havens in the General Scientific Meetings. The type of child that we see as the allergic child is told that his cold, his continuous anorexia and all his allergic manifestations are frequently due to the foci of infection in his tonsils, but the fact that this child may have anorexia, frequent colds, bronchitis and asthma due to fundamental physiologic instability has not been widely recognized. Dr. Wingate Todd made a wide study of the so-called allergic cripple and in that study he showed that anatomic deviations from the normal are responsible for much of this child's difficulties. He concluded that the hypertrophy of the tonsil is inversely proportional to the mineralization of the body and that it is not due to an infectious process in the majority of cases. In our work my associates and I have not been interested in the allergic paroxysm itself. We have been interested in studying the child as a whole, and here we find the same as has been shown by Todd, that there are marked deviations in general physiology from the normal standards. It has been our attempt to approach this child not from the standpoint of his allergy but from his physiologic deviations; and we have found that, as the body mineralization improves and his physiologic reactions become more stable, the respiratory infection and other symptoms which appeared in the form of allergy disappear and the tonsils subside behind the tonsillar pillars.

The First Object of Research.—Harvey has been called the "Father of Physiology," but Harvey was a physician. The fact that there were no pure physiologists in those days, and that Harvey might be regarded as representing physiology in his time, is irrelevant to the point that is being made. I am using this great physician's work as an illustration of how contact with patients inspires and leads to research on the normal functions of the body; it is a perfect illustration of how clinical medicine can react upon related science: in this instance actually beginning to form a science. Whatever else Harvey did he undoubtedly discovered the systemic circulation; and it is very apt here to point out that this discovery in particular, and the more complete statement of the circulation into which he wove it, was based in very large part upon experiments carried out upon the human being, the first object of research to which a physician naturally turns.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

SPONTANEOUS PNEUMOTHORAX IN COLLEGE STUDENTS

STAIGE D. BLACKFORD, M.D.
UNIVERSITY, VA.

Pneumothorax is commonly considered to be due to tuberculosis of the lung until proved otherwise. It has been said that in hospital and sanatorium practice 80 per cent or more of the cases of pneumothorax are of tuberculous origin, but in many such institutions patients are admitted primarily because of tuberculosis and the pneumothorax is generally only incidental. Pneumothorax may rarely occur in the early stages of clinical tuberculosis, but ordinarily when present in this disease it is a late complication. In late years it is being recognized that pneumothorax occurs in apparently healthy persons, and the opinion is gaining ground from such instances that the condition is often entirely unrelated to clinical tuberculosis. Many names have been applied to this type of pneumothorax, such as "pneumothorax in the apparently healthy," "benign spontaneous pneumothorax" and "pneumothorax simplex." Perhaps the best name suggested is "idiopathic spontaneous pneumothorax." This condition not only occurs in the apparently healthy but is usually characterized by an afebrile benign course with recovery in a few weeks.

The most exhaustive study of the cause of pneumothorax in the apparently healthy was made by Kjaergaard¹ in 1932. He reviewed the literature and found six cases in which the lesion had been "elucidated anatomically at autopsy." In these six cases the cause of the pneumothorax was rupture of the superficial air vesicles at the apexes of otherwise healthy lungs. Three of these vesicles resulted from multiple congenital malformations of the lung (or lung cysts). In the other three, solitary air vesicles had formed on a base of cicatricial changes. Microscopic examination had demonstrated that the base of these vesicles included a valve like structure as a result of scar tissue. The valve had allowed gradual distention of the vesicles until finally rupture had occurred. Kjaergaard further described his own study of three superficial lung vesicles without pneumothorax discovered in routine autopsies. The vesicles in two of these cases occurred on a scar tissue basis. He originally thought that the vesicles in the third instance resulted from a valve mechanism due to local emphysematous change, but in a subsequent communication² he made a note to the effect that he had changed his mind about this case and he attributed this vesicle to a congenital malformation of the lung. In this second publication in 1933 he reported in detail two additional cases of his own in which pneumothorax occurred in elderly persons without symptoms from rupture of congenital lung cysts. Perry³ concludes his discussion of the etiology with: "The immediate cause of a spontaneous pneumothorax is probably always rupture of an air-containing vesicle into the pleural cavity. They are said to be due either to congenital defect, to fibrous valvular obliteration of the smaller

bronchi or to localized emphysema. There does not seem sufficient evidence to decide at present which of these is the most important cause."

The true incidence of idiopathic spontaneous pneumothorax is difficult to determine because it is well recognized that the condition occurs with little or no symptoms. The so-called silent pneumothorax is probably not infrequent. Wilson⁴ has reported finding five cases without symptoms in routine chest roentgenograms of Yale students during a four year period. He mentions that others have had similar experience. As previously noted, incidental silent pneumothorax has been reported at autopsy.¹ Further, it seems likely that many cases of mild or atypical symptoms of pneumothorax have been diagnosed pleurisy, intercostal neuralgia, muscle strain or something else. In spite of an interest in the condition, I know of three instances in which I failed on initial visits to recognize the presence of pneumothorax. If every case presenting chest pain or dyspnea could be studied with x-rays, no doubt many more cases of spontaneous pneumothorax would be identified. Pneumothorax without symptoms or with slight and atypical symptoms is probably a fairly common condition.

As for the incidence of idiopathic spontaneous pneumothorax with symptoms, there appears to be a difference of opinion. Kjaergaard found fifty-one cases in the hospitals of Denmark in a careful search over a twenty year period and concluded that the condition was "very rare," although he added that it had been observed more frequently in the five years preceding his publication. Perry, reporting eighty-five cases found over a fourteen year period at the London Hospital, remarks that it is a "comparatively rare disease." He found twenty-six cases in the first seven years of this study and fifty-nine in the second seven years. On the other hand, Wilson states that "spontaneous pneumothorax has come to be recognized as a fairly common clinical entity." There are at least three large series⁵ in the American literature, containing nineteen, twenty-six and seventy-one cases respectively that have come under observation of one group or one individual. Kjaergaard, Perry, Wilson and others agree that young males are particularly susceptible to the condition, which fact was previously emphasized by the French name "pneumothorax of the conscripts." Wilson says "the increasing study of large groups of young individuals in schools, colleges, camps and industry has revealed many cases." He mentions that he recognized six cases from symptoms in Yale students in four years.

The problems of pneumothorax in college students is largely one of "pneumothorax in the apparently healthy," since college students are presumably "apparently healthy." With the exception of the cases already cited from Wilson's paper, it seems that little attention has been focused on this aspect of the health of college students.

In the present study fifteen cases of pneumothorax proved by roentgenograms have been recognized from symptoms in an average male student body of 2,500 at the University of Virginia. That this condition is not infrequent in college students is attested by the fact that eleven of these cases have occurred in the past

five years, or approximately one case per thousand students in a session. My purpose in this presentation is to discuss idiopathic spontaneous pneumothorax and to report our experience in these fifteen symptomatic cases encountered in the student body of the University of Virginia. In this discussion the excellent articles by Kjaergaard, Wilson and Perry are freely used, and those interested may refer to these reviews for a full bibliography.

Exertion per se is not a necessary precipitating factor. Laughing, coughing, sneezing, straining at stool, coitus and running have all been reported as the immediate cause, but many cases occur while the patient is resting in bed or in a chair. A third of Perry's patients were seized with pain in the early morning. In my experience also the onset has often been in the early morning: once while getting out of bed, once while dressing, once while shaving and several times while going to breakfast or early class. However, in at least three instances the first symptom was noted while the patient was relatively quiet (sleeping, studying and waiting for a bus).

When symptoms occur, their onset is usually very abrupt. Pain is almost invariably present and is generally the first symptom. It may be so agonizing as to require morphine, or it may be so mild that it is described as "oppression" or a "heavy feeling." It may be located from the shoulder to the upper part of the abdomen and it is usually located on the side involved; but rarely, as in one of our cases, it may be on both sides in a unilateral lesion. Once I found all the pain located substernally. Although the pain persists between respirations, it is ordinarily exaggerated by a deep inspiration. The intensity of the pain may increase for several hours before it gradually begins to subside. In several of our patients it persisted in a milder form for several days, and in a few instances it was an exaggeration of discomfort several days after onset which first made the patient seek medical advice. Pain or discomfort of some variety was present in all our series. A reflex cough, with or without sputum, may be an early symptom, but it was not a major one in our cases. Dyspnea may be absent, mild or marked. It was a complaint in eight of our group. It may occur as an early symptom or it may be noted only on exercise several days later. The rate and degree of the pulmonary collapse are said to determine the kind and amount of dyspnea. Although cyanosis may rarely occur, we have not seen it. The clinical picture of medical shock has been described in some cases. In the early stages it was probably frequent in this series, judging from the descriptions given, but only once was the picture of severe medical shock actually observed. It has been pointed out that cases presenting a febrile course are presumptively not due to idiopathic pneumothorax, and in none of our patients was there a significant or prolonged fever.

The physical signs of pneumothorax (i. e. suppression of tactile fremitus and suppression of voice and breath sounds) are said to be present in all cases. Perhaps they always are present but unless the possibility of pneumothorax is constantly borne in mind it is very easy to fail to detect them in a routine chest examination, especially when the layer of air is thin. Inspiratory lag and hyperresonance become more detectable as the collapse becomes more complete. In complete collapse there may be a shift of the mediastinum and depression of the diaphragm. Amphoric and metallic

auscultatory phenomena are not commonly found in spontaneous pneumothorax. The signs of fluid in the pleura are found only in the rare cases of hemopneumothorax. Careful chest films furnish the most exact method of diagnosis, and fluoroscopic examination alone is not reliable. In one of our cases, fluoroscopy failed to reveal the collapse subsequently demonstrated in films. Roentgenograms determine the degree of collapse and allow one to follow the course of reexpansion. Kjaergaard¹ classifies the degree of collapse under five headings:

1. Partial pneumothorax.
2. "Coat-formed" pneumothorax.
3. Total pneumothorax without displacement.
4. Total pneumothorax with moderate displacement.
5. Tension pneumothorax.

Our cases of pneumothorax by this classification were grouped as follows: partial five, "coat-formed" six, total without displacement three, total with moderate displacement one, and tension none.

Routine laboratory examinations are usually negative. Examination of the sputum for acid fast organisms is important. No acid fast organisms were found in our group. The most important procedure is the tuberculin test. In the limited reports available there appears to be little if any increase in the percentage of positive tuberculin reactions over that in normal groups. A positive reaction does not mean clinical tuberculosis but a negative one virtually excludes this etiology. Unfortunately this important test was performed only once in our series and in this instance it was negative.

In college students the chief problem in differential diagnosis is to exclude clinical tuberculosis. The lack of a history suggesting tuberculosis makes it unlikely. The tuberculin test, if negative, is most helpful. Careful study of the roentgenograms while the collapse is still present is not always dependable but, after reexpansion, physical and x-ray examinations of the chest may be relied on. No physical or x-ray signs suggestive of tuberculous activity were found in our cases, although several films exhibited calcium deposits and one case gave evidence of calcified miliary tuberculosis which appeared to be definitely healed.

Five main clinical types of pneumothorax have been described:

1. Chronic pneumothorax.
2. Hemopneumothorax.
3. Recurrent pneumothorax.
4. Alternating pneumothorax.
5. Bilateral pneumothorax.

We have not encountered a definite chronic pneumothorax nor have we recognized hemopneumothorax. We have had three cases of recurrent pneumothorax. One of our patients had five episodes of pneumothorax on the same side during his college career but he has had no recurrence in the past thirteen years. Another student had a second pneumothorax after leaving college but has been well for two years. There was still some air in the pleura of the third patient four months after the original episode, which was probably a recurrence, but this may have been a case of "chronic pneumothorax." A fourth case was difficult to classify because the patient suffered collapse of one lung exactly one month after he had had an almost complete collapse of the other, which had not entirely reexpanded. This case should probably be classed as alternating, since no heroic measures were necessary as they would have been in the bilateral type.

Rest in bed is all the treatment usually required in most cases of idiopathic spontaneous pneumothorax. No additional therapy was required in any of our cases. The period of rest depends somewhat on the degree of pneumothorax, but since our experience with the condition has increased the period of bed rest has shortened. Our most recent patient, who had a total pneumothorax without displacement of the mediastinum, was advised to remain in bed at home for three weeks but it was subsequently learned that he stayed in bed for only one week. His lung reexpanded in a total of three weeks and he made an excellent recovery. Kjaergaard¹ recommends a minimum of two weeks' rest in bed but Perry says that rest in bed for one week should be sufficient to allow the perforation to heal even in the more severe attacks. He points out that after healing the condition is unaffected by exertion. Tension pneumothorax requires immediate puncture, which may have to be repeated. Aspiration may be tried in chronic pneumothorax. Kjaergaard¹ says that injections of 30 cc. of 30 per cent dextrose solution may be used as a last resort in chronic, recurrent or alternating pneumothorax. Complete rest with morphine is necessary in hemopneumothorax, and ligation may even be attempted. The mortality is 37 per cent in reported cases. Bilateral puncture with continuous aspiration must be used when there is simultaneous collapse of the two lungs. Half the recorded cases have been fatal.

The prognosis in simple idiopathic spontaneous pneumothorax is excellent. The condition may recur once or several times, but the patient survives. Although tuberculosis may be a common cause of the scar tissue to form the valvelike mechanism necessary to the vesicle formation in pneumothorax, it is extremely rare that clinical tuberculosis develops as a sequel to the pneumothorax of the apparently healthy. Kjaergaard¹ in a careful study found that only one case of clinical tuberculosis had developed in forty-nine subjects in a period of observation covering a minimum of two years. Perry reexamined fifty-five of his eighty-five patients physically and radiologically without finding evidence of subsequent pulmonary tuberculosis, and twelve others were traced and known to be alive and well. He says further that "in a survey of the literature which included about 250 recorded cases of benign pneumothorax, it has been possible to find a record of only six developing chronic pulmonary tuberculosis." He points out that the incidence of tuberculosis in patients who have had a benign spontaneous pneumothorax is no higher than in the general community. Fourteen of our fifteen patients have been followed and are known to be in good health now after periods ranging from eight months to fifteen years. Four of these fourteen patients experienced their pneumothorax more than five years ago.

CONCLUSION

Spontaneous pneumothorax occurs not infrequently in college students. The sudden onset of chest pain or dyspnea should suggest the possibility of this diagnosis, and all patients with such symptoms should have x-ray examinations of the chest. If pneumothorax is found, the patient should be confined to bed for a week from its onset. No after-care is necessary because recurrences cannot be prevented by any known treatment. These patients should not be diagnosed as tuberculous or given treatment for tuberculosis unless some positive evidence of tuberculous activity has been demonstrated.

PREVENTION OF IGNITION OF ANESTHETIC GASES BY STATIC SPARK

PHILIP D. WOODBRIDGE, M.D.

BOSTON

J. WARREN HORTON, Sc.D.

Associate Professor of Biological Engineering, Massachusetts
Institute of Technology
CAMBRIDGE, MASS.

AND

KARL CONNELL, M.D.

BRANCH, N. Y.

As a result of our investigation of a fatal anesthetic explosion in Boston in October 1938, a means of preventing ignition of anesthetic gases by static spark has been devised which we believe to be of sufficient value to warrant general adoption in climates in which static sparks are frequent.

The explosion in question occurred despite the presence of from 60 to 65 per cent relative humidity in the operating room, electrical connection by chain between the operating table, the gas machine and the floor, and connection between the gas machine and the patient by wire wound around the breathing tubes and embedded in the rubber of the mask and thence by dangle chains to the patient's face. The floor was of terrazzo with

Fig. 1.—Danger from a charged person approaching a gas leak, as in the reported case.

embedded brass grids and was grounded. The anesthetist's stool was of painted metal with rubber feet and was covered with a sponge rubber pad finished with a felt-like cloth and protected by a casing of a textile similar to oilcloth or fabricoid. The mask was held in place by a rubber strap passed behind the patient's head. No electrical apparatus was in use other than the usual floor and ceiling lights. Cyclopropane had been administered by the carbon dioxide absorption method in the closed circuit of a Connell DeLuxe machine for about twenty-five minutes. Oxygen had been running at about 250 cc. a minute, no cyclopropane had been added for the last ten minutes and the bag had been staying about half full. It appeared, therefore, that there was no gross leak. As the wound was about to be sutured, the surgeon left the table and had reached a corner of the room when the explosion occurred. There was no other approach to or departure from the vicinity of the operating table and gas machine.

After the explosion the mask was still strapped to the patient's face, with the cushion ruptured. The posterior pharyngeal wall was lacerated, blood oozed from the trachea, subcutaneous emphysema developed rapidly

and the patient died about fifteen hours later. The machine was damaged, the rubber parts being ruptured throughout. Accessible parts of the breathing circuit were found drenched with water, apparently ample to couple electrically the patient and the machine up to the time of the explosion. The inspiratory flutter valve was jammed into its seat and the expiratory valve was blown off the machine, indicating that the explosion started not in the machine itself but in the vicinity of the mask and breathing tubes.

At a later date conditions were set up which duplicated as nearly as possible those existing at the time of the explosion, and various observations were made. Even in the presence of approximately 65 per cent rela-

Fig. 2.—Danger from placing intercoupling wires on or in the breathing tubes.

tive humidity, sparks of sufficient intensity to ignite explosive mixtures were obtained. The magnitude of charges which could be developed was measured by an electrostatic voltmeter. The most important finding was that an anesthetist wearing cotton garments acquired a potential of several hundred volts merely by sliding forward on the cushioned stool and then rising. When woolen street clothes were worn, the potential was considerably greater. Other less dangerous sources of potential were observed. A draft of air accompanying the opening of a door raised the potential of the operating table 50 volts. The placing of the

Fig. 3.—Danger from gas leaks in the absence of intercoupling.

drapes gave the patient a potential of 40 volts to ground. The insertion of gauze pads between the sterile sheet and the neck raised the patient's potential 150 volts. The removal of the stand for the instrument tray from the foot of the table gave the patient a potential of 50 volts. The investigation led to the conclusions which follow:

1. Adequate protection against electrostatic sparks is not necessarily obtained by providing a relative humid-

Read before the Section on Miscellaneous Topics, Session on Anesthesia, at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

ity as high as 60 per cent. It has been suggested that air conditioning equipment of the air washing type, as in this case, may remove carbon dioxide or other electrolyte from the air and thus defeat one of the main objects of humidification. The effects of atmospheric conditions on electrostatic phenomena are being investigated further.

Fig. 4.—Intercoupling of patient, gas machine, anesthetist and table.

2. Cushions on the anesthetist's stool constitute such a serious hazard that they should not be permitted. It is quite possible that the explosion in this case occurred as a result of a spark between the anesthetist and the patient after the anesthetist had slid forward on the stool (fig. 1). In other cases similar unsuspected factors may precipitate explosions if the protective measures which we advise are not used.

3. Intercoupling near the gases, as by wire wound around the breathing tubes and metal contact to the patient's cheek, is believed to present the following

Fig. 5.—Danger to patient through low resistance intercoupling in the presence of defective electrical equipment.

serious hazard: If, when the mask is being removed, the interruption of the connection between the chain and the face should occur simultaneously with some event tending to produce a charge on the patient or on the machine, there might well be a spark discharge between the face and the chain. This spark would of necessity occur directly in the spill of explosive gas from the machine (fig. 2). There is a further hazard due to the possibility of a break in the wire where it is embedded in the rubber. This break may occur in such a way as to introduce a spark gap directly into the explosive mixture. If metallic electrical connection is to be maintained between the patient and the gas machine, the conductor should be placed at a distance

from the breathing tubes and mask. It must be so arranged that it need never be disconnected while explosive gases are present, because disconnection of an effective conductor will produce a gap across which a spark could jump.

4. Previous reports as to the hazard involved by wool and silk were confirmed. Woolen blankets and silk and woolen outer garments should never be allowed near explosive gases. Undergarments of either silk or wool do not constitute an electrical hazard. To produce a charge from such fabric it is necessary first to rub it with some other material and then to separate the two. If the two are not separated there can be no electrical potential.

5. It was immediately obvious that the ideal method for completely removing the possibility of an electro-

Fig. 6.—Danger of increasing spark energy by low resistance intercoupling.

static potential between any two objects in an operating room, and thereby for preventing any spark discharge which might ignite an explosive mixture, would be to interconnect all objects and persons by conductors between these bodies or from these bodies to a conducting floor, which would then serve as a common interconnector. This method is believed to be impracticable

Fig. 7.—Safety through high resistance intercoupling.

with any means that have as yet been made available. However, it is possible by intercoupling to reduce certain specific hazards of frequent occurrence. The method here proposed is based on the assumption that under normal conditions of administering anesthetic gases no mixture of explosive concentration is likely to exist in an operating room outside a region of about a foot in radius surrounding any gas leak. Consequently considerable reduction in risk is obtained if the

occurrence of sparks within such restricted danger zones is prevented. The places where gas leaks most commonly occur are at the escape valve and between the mask and the patient's face. Gas also escapes from the breathing tubes and the patient's respiratory tract after the mask has been removed (fig. 3). Leaks may also occur at other points in the gas channels of the apparatus. If, therefore, the patient, the gas machine

Fig. 8.—No danger from short circuit to ground from defective electrical equipment through high resistance intercoupling.

and the anesthetist are so intercoupled electrically that sparks cannot occur between them, the major portion of all electrostatic potentials having dangerous possibilities is eliminated. The operating table may be included in this group with advantage (fig. 4).

There are two objections to electrical intercoupling when made by conductors of high conductivity, such as wire. One is the increased hazard from electrical shock. A patient forming part of such an intercoupling system suffers a greater chance of being grounded than does a patient not so connected and hence runs a greater risk of serious injury from accidental contact with the lighting circuit, as from defective electrical equipment (fig. 5). A second objection is that such an intercoupled group has greater electrostatic capacity than any one of its component bodies alone. This increase in capacity results in a more intense spark from any charged body that may make contact with the group (fig. 6). These two objections may be overcome by making the intercoupling connectors of high resistance, so arranged that

Fig. 9.—Reduction of tendency of intercoupled bodies to act as a single body of high electrostatic capacity by high resistance intercoupling.

the resistance between any two bodies in the intercoupled group is of the order of 1 megohm (1,000,000 ohms) (fig. 7). Such intercoupling limits any current from a 60 cycle, 110 volt lighting circuit which might accidentally pass through these connections to 0.1 milliamperes (fig. 8). Various published reports place the

minimal lethal current at from 50 to 100 milliamperes. Therefore through its possible connection of the patient to ground, 1 megohm intercoupling cannot subject him to a current of more than 1 per cent of the minimal lethal current.

One megohm intercoupling also effectively reduces the tendency of the intercoupled bodies to act as a single body of high electrostatic capacity. Although the group may receive more energy from any charged body than would one member alone, a considerable portion of the excess is dissipated harmlessly in the resistors (fig. 9).

Most important of all, the introduction of high resistance between the intercoupled bodies does not materially increase the time required for equalization of charges. Using the values of electrostatic capacity present in the interconnected group, as determined by actual measurement,¹ it has been found that any potential which may be established will be reduced to 1 per cent of its value in one one-thousandth second (fig. 10). This indicates that the duration of any charge which may be placed on any member of the group is extremely

Fig. 10.—Reduction of any potential to 1 per cent of its value in one one-thousandth second.

short. It also indicates that in most cases charges will be removed as rapidly as they can be put on and hence that dangerous potentials cannot be established. It is evident, therefore, that when connectors of 1 megohm resistance are used for intercoupling, electrostatic sparks between connected objects will be adequately prevented.

If the floor of the operating room is electrically conductive, it should be included in the intercoupled group. Then all persons with conductive shoes who enter the room and many other objects in the room will automatically join the intercoupled group through the medium of the floor. Similarly, connection to the building ground will bring all grounded bodies to the same electrostatic potential as the intercoupled group. In order that such grounding shall introduce no hazard of electrical shock, it must be made through high resistance. By bringing these additional bodies to the same potential, connection of the intercoupled group to the conductive floor or to the ground furnishes considerable additional protection against static spark.

1. Measurements of electrostatic capacities of the patient to the table, of the anesthetist to the ground and of the table to the ground have shown that the order of magnitude of any capacity involved in the interconnection is from 100 to 200 micromicrofarads.

A unit to maintain the desired interconnection has been made available.² It consists of a small metal case containing a network of resistors so arranged as to present four terminals, between any two of which there is a resistance of 1 megohm. The case itself forms one terminal, and from three other terminals run three wires. The intercoupler may be attached to the operating table and the three wires run to the gas machine, the patient and the anesthetist (fig. 11). It may, if more convenient, be attached to the gas machine and the wires run to the table, patient and anesthetist. Bracelets are used to make connection to the patient and anesthetist. Contact with a conductive floor may be made by a drag chain from the gas machine or by a wire from a fifth terminal with which some of the intercouplers are equipped. The fifth terminal may also be used for connection to the ground.

In the absence of such mechanical means of intercoupling, connection frequently exists through contact of the anesthetist's hands with the gas machine and with the patient (fig. 12). By some this is done without thought of the safeguard which it provides, but by others it is carefully planned and conscientiously carried out as a protection against static spark. However, any

Fig. 11.—Resistance of one megohm between intercoupled bodies by means of the Horton Intercoupler.

interruption, even though extremely brief, in the contact of the anesthetist with the patient and the machine, would introduce the possibility of a spark when contact is reestablished. We believe that such practice is too dependent on unremitting vigilance to be recommended.

Whatever method of intercoupling is used, all connections should be made before anesthesia is started and maintained until after the mask has been removed at the end of anesthesia and explosive gases have been flushed out of the machine and the patient. Any unintercoupled person or object must not be allowed near regions of possible escape of explosive gas (mask, breathing tubes or escape valve) without first making contact with one of the group at a point remote from such regions. Even if he is highly charged and a spark occurs, it will then be outside the danger zone of explosive mixtures and therefore harmless (fig. 13). If the anesthetist has to leave the group, he must reapproach the group in the same manner as should any other unintercoupled person.

The use of high resistance intercoupling in no way eliminates the need for other precautions against static spark. High relative humidity should be maintained where equipment permits, because it is an additional,

though unreliable, means of intercoupling. The carbon dioxide absorption method offers two distinct safeguards: Gases are not constantly blown out into the room to come in contact with various sources of ignition, and after the first few breaths the moisture within the apparatus furnishes a very considerable degree of protection against internal static spark. Additional protection would be provided by rapid dilution of any gas that does escape by a stream of air in the vicinity of

Fig. 12.—Connection through contact of hands in absence of mechanical intercoupling.

the mask and the escape valve. Rubber parts should be wet before they are used. Cloth covers should not be used on gas machines. To disconnect any portion of the breathing apparatus while it contains explosive gas is to invite danger, which is reduced but probably not always eliminated by intercoupling. The unnecessary and extremely dangerous habit of removing the breathing bag during anesthesia to dump its contents is probably responsible for more than one of the recent fatal explosions. If the bag hangs from the machine by a metal to metal slip joint, the two pieces of metal should be chained or wired together. If this is not done and the bag should fall, its collapse would force gas to flow through the newly created gap and at the same instant might produce a charge which could spark across that gap. One recent explosion may have occurred in this manner.

Fig. 13.—Safe manner for a body to approach intercoupled group: spark (if any) outside danger zone.

Protection against sources of ignition other than static spark does not fall within the realm of this discussion. Nevertheless a few warnings must be sounded. Too often it is forgotten that ether, vinyl ether and ethyl chloride form highly explosive mixtures in air, in oxygen and in nitrous oxide. It is frequently forgotten that

² Obtainable from the Technequipment Company, 9 Station Street, Brookline, Mass.

flushing inflammable gases from the machine with oxygen is extremely hazardous, that nitrous oxide supports combustion as does oxygen, and that a brief flushing of the patient and the machine with a nonexplosive mixture does not render conditions safe for the use of the cautery on the lung or on the neck. Machines are still in common use and are still commonly produced by some manufacturers through which gases may pass under high pressure from one tank into another. Electrical apparatus used in operating rooms is often astoundingly defective in design and in maintenance, cautery apparatus being among the worst offenders.

CONCLUSIONS

High resistance intercoupling is not a panacea against explosion, yet if properly carried out it will eliminate an important source of ignition that lies in the group frequently referred to as the most baffling to control, namely static sparks. Such intercoupling introduces no hazard in itself. The majority of the explosions presumably initiated by static spark that have recently come to our attention would have been prevented by this type of intercoupling.

NOTE.—Since this article was written, progress has been made by one of us (J. W. H.) in developing a method for the more nearly complete elimination of dangerous electrostatic potentials from the entire operating room and from all persons and objects in it. A description of the method will be published as soon as experimental tests have been made and specifications prepared. Pending the development of this method and its installation in operating rooms, we advise intercoupling as described in this article.

605 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. EVERETT A. TYLER, Philadelphia: I want to compliment the authors on their fine presentation. However, let us keep our feet on the ground about the hysteria relative to anesthetic explosions, which has been aided by newspaper publicity. The relative incidence of explosions is very low. Explosions have occurred as long as explodable anesthetics have been in use. Static charges have always been with us. Explosions have occurred through carelessness or ignorance of the fact that static charges can be generated by moving or rubbing rubber parts of machines. Many of these could have been avoided by properly grounding the anesthetist and the machine or by deliberate grounding by the anesthetist of himself and the machine before moving the rubber part. Explosions other than by static have occurred either from faulty construction of ether vaporizer-suction apparatus or by ignorance in trying to use a cautery or electric scalpel in a stream of explodable gas. As the authors pointed out, the use of a tight, completely closed method of administration of explodable anesthetics will contribute to increased safety, particularly if too much pressure is not used in the rebreathing bag. This is emphasized by the observations of Dr. Connell with regard to cyclopropane that, with a leak of 4 liters a minute at a point beyond 4 or 5 inches from that leak, the gas is so diffused that no explosion can occur. Certain explodable anesthetics are of great value and cannot at present be entirely superseded by other nonexplodable forms. Let us not ban an explodable anesthetic given by a completely closed system for one in which a completely open system is used and the explodable gas diffused throughout the operating room, the concentration of the gas in the operating room depending on the length of the anesthesia and the efficacy of room ventilation. Let us take all the precautions possible to avoid static, namely humidity, ventilation, the Horton intercoupler, rubber parts moistened with calcium chloride, discontinuance of wool blankets in operating room, discontinuance of rubber soled shoes and static producing covers on the anesthetist's stool and so on but withhold judgment as to the value of these precautions and the banning of certain anesthetics until

the committee of which Dr. Woodbridge and Professor Horton are members can present definite scientific conclusions.

DR. RALPH M. WATERS, Madison, Wis.: I shall not discuss the subject except to emphasize Dr. Tyler's word of caution that we do not get hysterical about this and that we use more sense until we know more about it. I should like to mention points of view that differ from the authors' but time forbids.

DR. ARNO B. LUCKHARDT, Chicago: In addition to the precautions that have been mentioned here, I should like to propose a few items for consideration, namely that perhaps some catalyst inside the machine, perhaps metal acting on gases that are highly explosive and somewhat under pressure, may lead to an explosion. All of us remember during our studies in chemistry what a powerful catalyst platinum black is, and that it will effect readily and at ordinary temperature marked chemical reactions which ordinarily take place only at higher temperatures. I have also considered that certain substances in the expired air of the patient might act as such a catalyst. And, third, the air in the room might be ionized by radium in order to dissipate electrostatic charges. This last suggestion is not new. Dr. Burger of New York got the same idea and is now working in a practical way on its solution, namely the use of slag in the isolation of radium from carnotite or from the isolation of uranium salts, which slag might be incorporated in the walls of the operating room and, by ionizing the air, dissipate electrostatic sparks. The time of "questionmairing" is over. It is time to do some laboratory work on the subject, which I tried to have done in 1924 when I attempted to get an appropriation from or through the University of Chicago and was simply told to write another paper on the dangers of the static spark and its dangers. The problem did not seem "fundamental" enough although it was sufficiently important to save the lives of countless human beings who were being operated on daily the world over, under ether anesthesia, nitrous oxide-oxygen-ether, ethylene-oxygen or cyclopropane-oxygen anesthesia. One anesthetic death as the result of an explosion while using the aforementioned anesthetics and occurring when the wife or daughter of a member of one of the officials of the monied foundations was on the operating table would result in a real investigation by competent physicists working in conjunction with biochemists and anesthetists. But this has not occurred. Until it does, thousands of dollars will be allocated for the study of such "fundamental" problems as "psychoanalysis" and similar medical fads.

J. W. HORTON, Sc.D., Boston: Ionization has already received consideration. Computations show that it would be necessary to increase the ionization in the air some thousand-fold over the maximum summer ionization, and the significance of that is that ionization due to natural causes is undoubtedly not the reason for the reduced number of explosions in the summer. Any means of ionization must be carefully watched, to make sure it does not produce ozone, because ozone and ethylene and ozone and cyclopropane are spontaneously combustible. As to the hysteria, as a physicist I sympathize with that point of view. However, when an anesthetist comes to you and says "I had an explosion today, what can I do to prevent that explosion from occurring again tomorrow?" we feel that something analogous to the intercoupler should at least be recommended, realizing that it is by no means ideal and we certainly hope not the final solution to the problem.

Legal Procedure for Hospitalization.—The legal procedure for the certification and commitment of an individual as insane is in general the same for the various European nations as for the various states of the United States. On the request of a relative of the patient or of some other interested party, the patient is examined by one or two physicians who write out a certificate stating their findings and recommendations for commitment. This certificate, usually with the relative's written consent to commitment, is then sent to the local magistrate, who legally certifies the patient's insanity and provides for his commitment and detention in a mental institution.—Landis, Carney, and Page, James D.: *Modern Society and Mental Disease*, New York, Farrar & Rinehart, Inc., 1938.

TREATMENT OF PNEUMOCOCCIC
PNEUMONIAWITH CONCENTRATED ANTIPNEUMOCOCCUS
RABBIT SERUMW. BARRY WOOD JR., M.D.
BALTIMORE

Although rabbit immune serum was first used in the treatment of pneumonia in 1891¹ it was completely neglected as a therapeutic agent until 1937, when its use was revived by Horsfall, Goodner, MacLeod and Harris.² A systematic investigation of the antibodies contained in antipneumococcus horse and rabbit serums had been in progress at the Hospital of the Rockefeller Institute for several years and the results of these studies led Horsfall and his co-workers to conclude that antipneumococcus rabbit serum might possess certain practical as well as theoretical advantages over horse serum in the treatment of pneumonia. Among the advantages stressed were the following:

1. Unconcentrated rabbit antiserum has a relatively high mouse protection potency as compared with unconcentrated horse antiserum.²

2. The antibody contained in antipneumococcus rabbit serum is three or four times smaller than that contained in horse antiserum and might therefore be expected to penetrate infected tissues more readily.³

3. More than optimum amounts of horse antiserum inhibit the protective action of the serum in mouse protection tests, but no such "prozone" phenomenon can be demonstrated with rabbit serum.⁴

4. Rabbits may be immunized in four weeks,⁵ whereas six months may be required to obtain potent horse serum.

5. The cost of production of rabbit antiserum is estimated to be considerably less than that of horse antiserum, especially for the rarer types of pneumonia, for which it is desirable to produce relatively small amounts of serum.²

Very few reports have been published on the use of antipneumococcus rabbit serum in the treatment of pneumonia. Horsfall, Goodner, MacLeod and Harris reviewed twenty-two cases in 1937, and Horsfall, Goodner and MacLeod⁶ added a second series in 1938, bringing the total to sixty-seven cases. More recently Loughlin, Bennett and Spitz⁷ presented an analysis of

sixty-nine cases and Nissen⁸ in Copenhagen mentioned a series of 100 cases but published the clinical data on only thirty-one. Unconcentrated rabbit serum was used in all the cases included in these earlier reports, and, although concentrated rabbit serum has been employed in several large clinics in this country for more than a year, little data relating to its clinical use are as yet available.

Finland and Brown⁹ have recently published the results of the treatment of pneumonia with concentrated rabbit serum in forty cases, and the records of five cases (in addition to three of treatment with unconcentrated rabbit serum) are included in Bullowa's monograph "The Management of the Pneumonias."¹⁰

My purpose in this paper is to report a series of fifty cases of pneumococcic pneumonia treated with concentrated antipneumococcus rabbit serum and to review briefly the data now available regarding rabbit serum treatment in general. It is thought advisable to summarize the data on rabbit serum in order that they may be made available for comparison with results obtained with sulfapyridine, a chemotherapeutic agent which appears at present to offer a highly effective and practical method of treating pneumococcic infections.

METHODS

Case Material.—During the past year seventy-one patients, fifty-eight in the Johns Hopkins Hospital and thirteen in the Union Memorial Hospital,¹¹ were treated with concentrated antipneumococcus rabbit serum. All patients suffering from pneumonia due to pneumococci of types I to VIII and XIV were treated with antiserum except when there was a definite contraindication to protein therapy. Twenty-one patients received in addition to rabbit serum either horse antiserum or sulfapyridine, and they have not been included in the present analysis since it is impossible to evaluate the effectiveness of rabbit serum per se when it is used in conjunction with another specific therapeutic agent.¹² The significant clinical data on the fifty patients treated with rabbit serum alone are presented in detail. All patients treated have been included regardless of the amount of serum administered or the time of survival.

Bacteriology.—The typing of sputum was done by the Neufeld method and was confirmed by mouse inoculation and in a few cases by typing from ascitic fluid cultures. Blood for cultures was taken at the time of the patient's admission to the hospital and whenever indicated during the course of treatment. The blood cultures were made in blood agar, dextrose blood agar and dextrose beef infusion blood broth. Colony counts were made in cases of bacteremia.

Serum.—All the concentrated antipneumococcus rabbit serum was supplied by the Lederle Laboratories,

* Beginning of crisis † D = Died R = Recovered

serum therapy was begun. Treatment with antiserum was avoided if possible when there was a history of bronchial asthma.

Administration of Serum.—An initial dose of 1 cc. of therapeutic serum diluted to 20 cc. with physiologic solution of sodium chloride was slowly injected intravenously over a period of twenty minutes. One hour later a volume of serum containing approximately 50,000 units was injected undiluted or diluted to 20 cc. with physiologic solution of sodium chloride. This dose was repeated every hour until sufficient antibody had been administered. Whenever a thermal reaction was encountered the hyperpyrexia was allowed to subside before the next injection of serum was given. Therapy was not discontinued because of chill reactions. The chills were treated in some cases with intravenous injections of calcium chloride,¹³ and, although this substance occasionally terminated the rigor abruptly, it was found at other times to be quite ineffective.

Control of the Dose of Serum.—The total dose of antibody was controlled by means of the cutaneous test with the specific capsular polysaccharide¹⁴ in thirty-

six of the fifty cases.¹⁵ In those cases in which the Francis cutaneous test was not employed the serum was given more slowly, usually at from two to four hour intervals, and its administration was discontinued as soon as the temperature began to fall. The urine of critically ill patients was tested for specific polysaccharide,¹⁶ and whenever this was found even larger doses of serum were given, often as much as 100,000 units an hour.

RESULTS

The important clinical data taken from the hospital records of the fifty patients treated with concentrated antipneumococcus rabbit serum are presented in tables 1, 2 and 3. The cases may be divided conveniently into three groups: (1) those of pneumonia of type I, (2) those of pneumonia of type III and (3) those of pneumonia of types II, IV, V, VI, VII, VIII and XIV.

Type I: Twenty-four patients with type I pneumonia were treated with concentrated type I antipneumococcus rabbit serum. Eight had bacteremia at the time of admission, seven showed signs of multilobar consolidation and in three empyema developed. Treatment was begun on the average during the fourth day of illness, and the average time between the first injection of serum and the beginning of the crisis was nine hours. The average amount of serum used was approximately 300,000 units; the total amount given in each case varied from 50,000 to 700,000 units. Delayed serum sickness was observed in eleven cases and thermal reactions were encountered in five. Thrombophlebitis developed in one case at the site of injection of the serum. No anaphylactic reactions were encountered.

Of the four patients who died, all had multilobar consolidation, two were 82 years of age and a third was 68. The fourth patient was a 33 year old white man whose blood culture on admission showed forty colonies per cubic centimeter and who made an excellent response to serum therapy, with a prompt crisis, only to die two days later of cardiac failure during an attack of paroxysmal auricular fibrillation.

Type III: Type III pneumococci were isolated from the sputum of eight patients, all of whom were treated with concentrated type III antipneumococcus rabbit serum. The average age was 44, but three of the four patients who died were 65 or more. There was only one patient with bacteremia, but four had more than one lobe involved. Among the patients who recovered, the time between onset of therapy and beginning of

crisis varied from six to twenty-two hours. In three the response was dramatic and seemed to be related directly to the serum treatment. There were four thermal reactions and three cases of serum sickness. None of the patients had empyema.

A further analysis of the fatalities is of some interest. The only young patient who died of type III pneumonia was a 35 year old Negro admitted to the hospital in shock on the fourth day of illness. Three lobes were involved and there were physical signs of pericarditis. The blood culture was positive and the leukocyte count was only 4,000. In spite of vigorous intravenous therapy the patient failed to respond and died twelve hours after admission to the hospital. The other three fatalities were of elderly patients, all of whom showed clinical evidence of arteriosclerotic heart disease. One had auricular fibrillation and congestive heart failure and died of uremia after a fairly good response to serum therapy, and another died very suddenly of what was thought to be coronary occlusion on the day after crisis.

Types II, IV, V, VI, VII, VIII and XIV: The last group is a heterogeneous one composed of a single case of type II pneumonia and seventeen cases of pneumonia due to pneumococci of the "higher types." These are considered together only because there are too few for separate analyses according to type. The average age was 37. Four patients had more than one lobe involved, and three had bacteremia. On the average, treatment was begun on the fourth day of illness and the dose amounted to approximately 240,000 units of antiserum. It should be pointed out that in case 1 (type VIII) and case 2 (type IV) treatment was probably begun at about the time of natural crisis, since only a very small amount of antibody was required to bring the temperature to normal. Fifteen of the sixteen patients who recovered responded well to therapy, crisis occurring within one to sixteen hours after the first injection of serum. The sixteenth patient failed to have a crisis, and the temperature remained elevated for more than two weeks. The course of his illness was complicated, however, by the presence of a severe infection of the urinary tract. Thermal reactions were encountered in six cases and serum sickness in four. There was no empyema.

Of the patients who died the first was a 34 year old white man who entered the hospital on the fifth day of an attack of type II lobar pneumonia involving the lower lobes of both lungs. The white blood cell count was 4,000, and the blood culture showed 680 colonies per cubic centimeter. After 300,000 units of antibody was given the Francis cutaneous test became positive and the temperature fell to 101 F. Within a few hours, however, the temperature rose to 103 F. and signs of meningitis developed, and the patient died forty hours after admission to the hospital. Blood taken for culture just before death was sterile. Autopsy revealed purulent meningitis due to pneumococcus type II and extensive lobar pneumonia involving the lower lobes of both lungs. The second patient who died was a 31 year old white woman who had been suffering from attacks of severe bronchial asthma for several years. She was admitted to the medical ward two days post partum with pneumonia due to pneumococcus type XIV involving three lobes. The blood taken for culture at the time of admission was sterile. Because of the history of asthma serum was withheld for three days, but on the fourth day a second blood culture revealed seventy-

five colonies of type XIV pneumococci per cubic centimeter and it became apparent that the pneumonia was progressing rapidly. Serum therapy was begun with great caution. In spite of the fact that all the sensitivity tests were negative and the patient showed no reaction to the first two injections of serum, she died suddenly about five minutes after the third intravenous treatment. The sudden death suggested an anaphylactic reaction but the diagnosis could not be definitely established.

COMMENT

As has already been emphasized by Horsfall, Goodner and MacLeod,⁶ it is extremely difficult to prepare antiserum from either horses or rabbits which is

Beginning of crisis + D = Died R = Recovered

potent against type III pneumococci. It is necessary therefore to consider type III pneumonia separately in discussing the final results of serum treatment. There were four fatalities in the eight cases of treated type III pneumonia, giving a case fatality rate of 50 per cent, which corresponds closely with the figures reported by Horsfall, Goodner and MacLeod, six deaths in a group of thirteen cases. In spite of the apparent ineffectiveness of the serum in lowering the mortality rate of type III pneumonia, it should be repeated that certain patients seemed to respond dramatically to serum, as evidenced by a prompt crisis. Also it is worth mentioning that seven of the ten fatalities were in patients over 57 and the other three in patients who had bacteremia at the time of admission to the hospital. Although these facts suggest possible explanations for the high case fatality rate of the type III pneumonia treated with rabbit serum, there is no conclusive evidence as yet that specific antiserum prepared either from horses or

from rabbits is effective in the treatment of type III pneumonia. The cases of type III pneumonia therefore will not be considered in the following discussion.

A summary of the most important clinical data obtained in the present series of forty-two cases of pneumonia treated with concentrated antipneumococcus rabbit serum is presented in table 4. Certain points are worthy of special emphasis. Eight different types of pneumonia were treated, and the pneumonia encountered was moderately severe, as evidenced by the presence of bacteremia in 26 per cent of the cases and multilobar consolidation in a like percentage. Treatment was begun rather late in most of the cases, the average first day of treatment being the fourth day of

data from the remaining 237 cases is presented in tables 5 and 6 and when briefly analyzed reveals the following important facts:

- 1. The high incidence of bacteremia (33.8 per cent) indicates that the pneumonia of the patients treated with antipneumococcus rabbit serum was of more than average severity.
- 2. The case fatality rate of 9.3 per cent was considerably lower than that reported in any similar series of cases of pneumonia treated with antipneumococcus horse serum.
- 3. The average total dose of rabbit serum (units) used in these cases was somewhat larger than the usual total dose of horse serum.

† Beginning of crisis.

illness. Approximately 275,000 units of antibody was required on the average to bring about the desired therapeutic result, a total dose which is relatively large as compared with the amounts of horse serum usually recommended for the corresponding types of pneumonia. All but six patients recovered, and in the majority of cases the response to serum therapy was prompt, the time from the first injection of antiserum to the beginning of crisis averaging only eight hours. There were three cases of empyema, the pneumococci in all being of type I. Reactions to the rabbit serum were relatively common; 26 per cent of the patients experienced thermal reactions to one or more injections of serum and 36 per cent had delayed serum sickness. It is of some interest that all the patients who failed to recover were extremely ill at the time of admission to the hospital, all having multilobar consolidation. The blood cultures of five showed more than five colonies of pneumococci per cubic centimeter, and the one patient whose blood culture was sterile was an 82 year old white woman who finally died of congestive heart failure and uremia.

The number of cases here reported is obviously far too small to warrant any general conclusions as regards the effectiveness of antipneumococcus rabbit serum. Previous publications regarding the use of rabbit serum have likewise dealt only with relatively small numbers of cases. All the cases, however, which have been reported to date,¹⁷ including the present series, total more than 260 and constitute a group sufficiently large to yield data of some statistical significance.

Twenty-six cases of type III pneumonia, twelve of which were fatal, were encountered in the collected series; these have not been included in the final analysis for reasons already mentioned. A summary of the

- 4. The incidence of empyema in patients treated with rabbit serum was no lower than that reported for patients treated with horse serum¹⁸ in spite of the fact that the rabbit antibody is smaller and might be expected to penetrate the pleura more readily.

§ Two patients with empyema treated in fifth and ninth weeks, respectively.
‡ Untitrated serum used by Horsfall, Goodner and MacLeod (fifty-four cases)⁹ and by Bullowa (one case).¹⁰

- 5. Thermal reactions were relatively common in patients treated with rabbit serum (50 per cent)¹⁹ as

18. Bullowa, J. G. M., and Mayer, Edgar: The Hazards of the Induction of Pneumothorax in the Treatment of Lobar Pneumonia, J. A. M. A. 105: 191 (July 20) 1935.
19. It should be emphasized that fewer chill reactions have been encountered with more recent lots of rabbit serum, and it seems likely that the incidence of thermal reactions may be lowered still further by improved methods of processing and refining.

17. Horsfall, Goodner and MacLeod.⁶ Loughlin, Bennett and Spitz.⁷ Nissen.⁸ Finland and Brown.⁹ Bullowa.¹⁰

compared with the generally accepted statistics for horse serum (20 per cent).²⁰ A higher incidence of chill reactions was encountered with unconcentrated serum (41 per cent).

6. Serum sickness developed in 41 per cent of the patients treated with rabbit serum, a morbidity rate significantly higher than the 19.8 per cent reported by Lord and Heffron²⁰ for concentrated horse serum. No appreciable difference was noted in the incidence of serum sickness in patients treated with concentrated and with unconcentrated rabbit serum.

CONCLUSION

Antipneumococcus rabbit serum, both concentrated and unconcentrated, has proved to be a highly effective agent in the treatment of severe pneumococcal pneumonia. Only in type III pneumonia does it seem to be ineffective as judged by the case fatality rate. Excellent results have been reported in the treatment of types I, II, V, VII, VIII and XIV pneumonia, the case fatality rates being even lower than those published recently by Bullowa¹⁰ and Finland⁹ for the corresponding types treated with horse serum. These data, however, do not offer convincing evidence that rabbit serum is more effective than horse serum, for the number of patients treated with rabbit serum is far too small for accurate comparison. Rabbit serum has

* Summary of cases collected from published reports.

been no more effective than horse serum in lowering the incidence of empyema. Very few anaphylactic reactions have been encountered with rabbit serum, but serum sickness and thermal reactions have been relatively common.

SUMMARY

Fifty patients with pneumococcal pneumonia of nine different types were treated with concentrated antipneumococcus rabbit serum. Eight patients with type III pneumonia were treated and four died, the serum seeming to be relatively ineffective with this type. For the remaining forty-two patients the fatality rate was 14.3 per cent, although 26 per cent of the patients had bacteremia and a like number had multilobar consolidation. Excluding the patients with type III pneumonia, all the patients who failed to survive had more than one lobe involved and all had more than five colonies of pneumococci per cubic centimeter in the blood culture except one, an 82 year old white woman who died of congestive heart failure and uremia. The incidence of empyema was 7 per cent. Thermal reactions were relatively common, occurring in 26 per cent of the patients, and delayed serum sickness developed in more than one third of the patients.

PARATHYROID INSUFFICIENCY WITH SYMMETRICAL CEREBRAL CALCIFICATION

REPORT OF THREE CASES, IN ONE OF WHICH THE PATIENT WAS TREATED WITH DIHYDROTACHYSTEROL

L. MCKENDREE EATON, M.D.

AND

SAMUEL F. HAINES, M.D.

ROCHESTER, MINN.

The roentgenographic finding of symmetrical cerebral calcification, particularly of the basal ganglia, is unusual, but the association of this condition with parathyroid insufficiency has been so frequent in our experience as to seem to justify this paper on the subject.

Symmetrical cerebral calcification (fig. 1) was first observed roentgenographically at the clinic in 1936. Since that time we have seen seven additional cases. The first six cases have been described elsewhere;¹ the seventh is included in this report. So far as we are aware, the three cases about to be reported are the first in which the roentgenographic observation of symmetrical cerebral calcification has been associated with parathyroid insufficiency. In at least seven cases of parathyroid insufficiency the characteristic pathologic changes in the brain were found at necropsy. In all these cases the calcification was of sufficient degree to have been observed roentgenographically had such an examination been made. Pick² reported the first two of these cases in 1902 and, a year later,³ a third. Weimann⁴ and Ostertag⁵ subsequently reported single cases, and Schnabel⁶ then added two more cases to the literature. Ostertag's patient had both tetany and Addison's disease.

REPORT OF CASES

CASE 1.—A schoolboy aged 13 years 7 months was brought to the clinic June 13, 1936, because of convulsive seizures. He had been considered healthy until the age of 7 years, when he had had his first convulsive seizure. These seizures had then continued to occur and had ranged in frequency from one a year to fifteen within twenty-four hours. More recently they had occurred on an average of once a month, the last attack having been on June 6, 1936.

The attacks were described as beginning with numbness and tingling in the left foot, followed by involuntary inversion of the foot and clenching of the right hand, forming a fist. This served as a warning to the patient and gave him time to

sit down before losing consciousness. With loss of consciousness his head and eyes turned to the right, twitching began in the right side of his face, his whole body became rigid, and he almost invariably fell toward the right. The seizures lasted one or two minutes and were then followed by a short period of mental confusion. Occasionally a minor seizure, characterized by numbness and tingling in the left foot, occurred without progressing through the complete sequence first described. In the opinion of the mother there had been definite slowing of the mental processes and an increase in clumsiness in the previous year or two.

The positive observations on neurologic examination included stammering grade 2 (on a basis of 1 to 4) and dysarthria grade 1. The patient walked with his arms hanging abducted about 6 inches from his sides and swung them less than was usual. His facial expression was somewhat immobile. The speed of movement of his tongue and of the alternate flexion and extension of his fingers (finger-wiggle) was diminished from 25 to 50 per cent. The deep tendon jerks were diminished about 50 per cent but were equal on the two sides. No abnormal reflexes or Chvostek and Trousseau phenomena could be elicited. June 15 the intelligence quotient, as determined by Terman's revision of the Binet-Simon test, was 73 per cent. The test gave an identical result when repeated ten days later after all sedative medication had been stopped.

Fig. 1 (case 3).—Typical symmetrical cerebral calcification.

Roentgenograms of the skull showed numerous small, irregular areas of calcification symmetrically distributed on either side of the midline in the region of the basal ganglia. On the left side, higher up in the frontal lobe and above the usual location of the anterior horn, there was another small, irregular

Values for Calcium, Phosphorus and Phosphatase (Case 1)

June 22, 1937.....	9.8	5.1	

area of calcification similar to the areas present in the basal ganglia. Roentgenograms of the heads of the mother, father and one brother who accompanied the patient were negative. Basal metabolic rates June 23 were plus 4 and minus 23 per cent. On the next day the rates were found to be minus 1 and minus 7 per cent.

Pneumo-encephalography (performed June 19) gave negative results except for showing the relation of the calcification to the ventricular system. The spinal fluid removed at the time

of this procedure was clear, the Kolmer and Kline tests were negative, the Nonne test for globulin was negative, there was one lymphocyte and 30 mg. of protein per hundred cubic centimeters, and the colloidal benzoin curve was 000 002 321 000 000.

June 18 the value for blood calcium was 6.8 mg., that for phosphorus 7.2 mg. and that for phosphatase 10.4 units per hundred cubic centimeters. June 24 the patient began to take, orally, twelve teaspoonfuls of powdered calcium lactate (approximately 24 Gm.) and three tablespoonfuls of cod liver oil (approximately 45 cc.) daily. The dose of calcium lactate was increased to eighteen teaspoonfuls June 27 and to thirty-two teaspoonfuls July 6.

The patient had three major seizures on July 5. At that time the level of serum calcium had not become elevated. By July 16 the serum calcium had risen to 9.2 mg. per hundred cubic centimeters. The values for serum calcium were normal Oct. 6, 1936, and June 22, 1937. When last heard from (December 1937) the patient was much improved; he appeared brighter, was doing well in school and had experienced no convulsions since July 5, 1936. He had continued to take calcium lactate and cod liver oil faithfully. Roentgenograms (made elsewhere) showed no appreciable change in the cerebral calcification.

CASE 2.—A girl was first seen at the clinic in 1925, when she was only 2½ years old, because of seizures of the grand and petit mal type of eleven months' duration. Three weeks before admission a corneal ulcer had developed. The essential finding at this examination was a level of serum calcium of 7.4 mg. per hundred cubic centimeters. A diagnosis of tetany was made and cod liver oil and calcium were advised. The patient improved rapidly and the attacks ceased. The patient was not seen again at the clinic until Sept. 29, 1937, not until which time did we learn that she had failed to develop properly; she had been unable to go beyond the second grade in school, had been difficult to control at home, had had frequent tantrums, and had not played normally with other children. The convulsions, of which she had two in the year prior to her first visit, had ceased and she had gone three years without a seizure. Her mother, father, two brothers and two sisters were all normal and there was no history of epilepsy or mental disease in other members of the family.

On general examination (she was 14 at this time) the patient was 54 inches (137 cm.) tall and weighed only 72½ pounds (33 Kg.). She was obviously mentally retarded. Her teeth were carious and malformed. The liver was palpable for a distance of 2 cm. below the right costal margin.

Ophthalmologic examination showed the vision of the right eye to be reduced to the ability of counting fingers at about 100 cm.; vision was 6/30 in the left eye. Both corneas were cloudy; the pupils and reflexes were normal. The optic disks appeared normal, but the rest of the fundus was poorly seen because of the corneal opacities. The patient cooperated too poorly for a test of the visual fields to be reliable.

Neurologic examination gave negative results except for showing the mental age of the patient to be 6 years. This represented an intelligence quotient of 42 per cent, classifiable as imbecility. The Chvostek and Trousseau phenomena could not be elicited.

Urinalysis, and a determination of the value for hemoglobin and of the erythrocyte and leukocyte counts, gave negative results. The Kline test of the blood for syphilis was also negative. Oct. 1, 1937, the blood serum contained 6.0 mg. of calcium, 7.2 mg. of phosphorus and 1.8 units of phosphatase; the serum protein was 7.2 Gm. per hundred cubic centimeters.

Roentgenograms of the thorax showed calcification of the hilar lymph nodes. Plain roentgenograms of the skull showed multiple small, irregular areas of calcification distributed symmetrically on either side of the midline in the region of the

basal ganglions. In addition there were smaller, less distinct areas of calcification in the cerebellar region, probably in the dentate nucleus.

Cod liver oil and powdered calcium lactate were prescribed after the method used by Boothby, which method was successfully employed in treating the first patient. Unfortunately, the second patient could not remain at the clinic for treatment and a follow-up could not be obtained.

CASE 3.—An unmarried woman aged 28, examined May 20, 1938, complained of convulsions and of pain and stiffness in many joints and muscles. At the age of 11½ years she had begun having attacks of severe generalized tonic and clonic convulsions and unconsciousness. These attacks had varied in frequency up to twenty a day and had lasted up to one hour each. Her memory had been poor since the age of 13. At 18 she had begun taking phenobarbital daily and the attacks had been less frequent and less severe; however, she had had minor attacks of "blankness" typical of petit mal, with tonic contraction of the left leg and of the right side of the body. These came as often as five times daily.

Three years prior to examination a rash had developed on the dorsal surfaces of the hands. This was diagnosed as pellagra and the patient was given a high vitamin diet, yeast and much milk. The rash then cleared and, during the time this diet was followed, the convulsions and minor attacks were much less frequent. About a year later pain and stiffness developed in many joints and muscles. The patient then underwent treatment for arthritis and had no convulsions for a year. In the six months preceding examination at the clinic she had three generalized convulsions and had up to five minor attacks daily in spite of the continued use of 4½ grains (0.27 Gm.) of phenobarbital daily. Visual acuity had diminished suddenly a few years previously, the approximate date of this being uncertain.

The patient's complexion was sallow and she responded slowly to questions. Her memory was defective and it was impossible to obtain a history which was dependable as to dates. She was found to have a mental age of 9 years 7 months, or an intelligence quotient of 60 per cent. Her knees were swollen, and extension of the legs was slightly limited. The joints were not red or tender. The Chvostek and Trousseau signs were strongly positive. Ophthalmologic examination revealed bilateral immature cataracts of the cortical type. Vision in the right eye was 4/60, in the left eye 3/60.

Roentgenograms of the skull (fig. 1) showed multiple symmetrical areas of cerebral calcification on each side in the region of the basal ganglions and in the subcortical white matter of the frontal, parietal and temporal lobes. Similar shadows were present in both cerebellar hemispheres. The calvarium showed a moderate degree of osteoporosis. Roentgenograms of the right ankle were negative except for showing a moderate degree of osteoporosis.

Chemical examination of the blood after fifteen hours of fasting revealed calcium 4.2 mg., inorganic phosphorus 5.2 mg., magnesium 1.8 mg., cholesterol 277 mg., cholesterol esters 208 mg., lecithin 266 mg., fatty acids 446 mg., total lipoids 723 mg. and sugar 79 mg. per hundred cubic centimeters. The blood sedimentation rate was 26 mm. in one hour. The basal metabolic rate was minus 10 per cent. Treatment of the parathyroid insufficiency was begun on June 1 with dihydrotachysterol (A. T. 10), calcium lactate and cod liver oil. The details are given in figure 2.

Linear extraction of the left lens was performed June 27, and on July 11 linear extraction of the right lens was performed after a preliminary discussion three days previously. Following these procedures, vision with the proper refractive correction was 6/6 for the right eye and 6/10 for the left.

As treatment progressed, the pains in the abdomen and muscles decreased, the patient became more alert, and mental improvement was noted. Her appearance and color also showed improvement. July 18 the intelligence quotient was again determined by the same observer and under the same conditions as before, and this time the test showed a mental age of 11 years, or an intelligence quotient of 69 per cent. Under the circumstances, this rise of 9 per cent seemed significant. No generalized convulsions occurred up to July 26, and the attacks of petit mal became less frequent and finally stopped. The patient attempted to discontinue taking the phenobarbital but was apparently afraid to stop it altogether.

In a letter dated March 30, 1939, the patient said she was much improved, was stronger, and had had no recurrence of the convulsions or petit mal seizures. Phenobarbital had been discontinued.

In 1936 Boothby and Davis⁷ reviewed the literature on parathyroid insufficiency and in this excellent review called attention to the various complications of chronic parathyroid insufficiency, particularly the development of cataracts, convulsions and trophic changes. They reemphasized the advisability of large doses of dissolved calcium lactate in the treatment of the condition.

In 1934 Holtz, Gissel and Rossmann⁸ described the use of dihydrotachysterol, a fraction of irradiated

Fig. 2 (case 3).—Treatment of parathyroid insufficiency with dihydrotachysterol, calcium lactate and cod liver oil.

ergosterol, in the treatment of parathyroid insufficiency, and in 1936 Arnold and Blum⁹ reported its use in three cases. Recently Albright and others¹⁰ have carefully studied its effect and have found that both it and vitamin D increase the absorption of calcium from the intestine and the excretion of phosphorus in the urine but that the phosphorus-excreting property of dihydrotachysterol is greater than that of vitamin D. MacBryde¹¹ found dihydrotachysterol to be more effective in the treatment of parathyroid insufficiency than cod liver oil and calcium. He, however, as have all writers who have used the drug, warned against the dangers connected with its use; since the effective dosage is very small, there is danger of giving too much of the drug. Large doses given to animals have produced decalcification of the bones and metastatic calcification.

10. Albright, Fuller; Bloomberg, Esther; Drake, Truman, and Sulzowitch, H. W.: A Comparison of the Effects of A. T. 10 (Dihydrotachysterol) and Vitamin D on Calcium and Phosphorus Metabolism in Hypoparathyroidism, *J. Clin. Investigation* 17:317-329 (May) 1938.

11. MacBryde, C. M.: The Treatment of Parathyroid Tetany with Dihydrotachysterol, *J. A. M. A.* 111:304-307 (July 23) 1938.

In case 3 the parathyroid insufficiency was fairly well controlled with cod liver oil and large doses of calcium lactate (about 60 Gm. daily). Such doses of calcium, however, caused severe diarrhea and it was felt that the greater ease of control accomplished by means of dihydrotachysterol and calcium lactate in smaller doses made the latter procedure worth while. It would seem from the response in this case, however, that dihydrotachysterol elevated the level of blood calcium more easily when combined with fairly large doses of calcium. As was to be expected, the maintenance of a normal level of serum calcium and phosphorus was accomplished more easily after the values for calcium and phosphorus had been elevated to normal.

COMMENT

Symmetrical cerebral calcification, particularly of the basal ganglions, produces a distinctly characteristic roentgenographic picture. Considerable variation in the degree and extent of this form of calcification may occur, corresponding to the stage of the disease at the time the x-ray examination is made. Calcium is always present microscopically long before it can be revealed by roentgenographic methods. This calcification first appears in the roentgenograms in the form of small, irregular, discrete, symmetrically distributed shadows. When the pathologic changes are more marked, the number of these shadows is increased and their distribution is more generalized; they occur even in other regions than the basal ganglions. In cases in which the deposits of calcium are unusually heavy, the discrete shadows seem to coalesce into a more or less homogeneous mass.

The basis for the x-ray picture is one of colloid deposition in and around the finer cerebral blood vessels, with subsequent calcification of the deposit. Only when the pathologic process is extreme can it be demonstrated roentgenographically. These changes are so frequently found at necropsy in the globus pallidus and dentate nucleus of the cerebellum that their presence to a slight degree, if not normal, is not unexpected. A marked increase in the degree and extent of the vascular process is likely to occur at any age, in either sex and in response to many diseases, not all of which need produce neurologic symptoms. The pathologic process has been most extensive and therefore most likely to be detected roentgenographically in parathyroid insufficiency and other diseases characterized by mental deterioration with or without convulsive seizures or motor symptoms referable to the extrapyramidal system.

Since adequate treatment of parathyroid insufficiency improves the mental condition of the patient and stops the convulsions without producing roentgenographically detectable changes in the cerebral calcification, we believe that the cerebral calcification itself is not responsible for the mental deterioration or the convulsive phenomena. Evidently, parathyroid insufficiency is only one of several diseases producing a disturbance of cerebral metabolism which results in the deposition of colloid material in and about the finer cerebral vessels. This deposit of colloid has a tendency to take up calcium even when parathyroid insufficiency does not exist. Thus it seems to us that symmetrical cerebral calcification, mental deterioration and convulsions are all concomitant cerebral symptoms of hypoparathyroidism, and one finding does not stand in etiologic relationship to the other.

We believe that the association of tetany with symmetrical cerebral calcification should be emphasized. Three of our seven patients had definite parathyroid insufficiency. In retrospect, another case (not reported here) may well have been one of this disease, although the diagnosis was never established. Seven cases of tetany have been reported in which postmortem examination revealed extensive cerebral calcification.

It has occurred to us that some of the cases of marked cerebral calcification associated with mental deterioration and convulsive seizures reported in the literature may have included a parathyroid insufficiency which was not detected. We believe, therefore, that the skulls of all patients with chronic parathyroid insufficiency should be examined roentgenographically. In addition, in all cases in which roentgenograms show symmetrical cerebral calcification, a determination of the serum calcium should be made in an effort to establish or exclude parathyroid insufficiency.

ABSTRACT OF DISCUSSION

DR. FULLER ALBRIGHT, Boston: I have one more case as further evidence that calcification of the brain in hypoparathyroidism does occur. A young boy who had an idiopathic hypoparathyroidism was seen a number of years ago and these same calcium deposits were demonstrated by x-ray examination. His case history appears in the *Annals of Internal Medicine* 12:1751 (May) 1939. The same type of pathologic change existed as in the case of Drs. Eaton and Haines. I would like to think that this tendency for calcium to occur in abnormal places in hypoparathyroidism indicates a tendency for the blood to be slightly supersaturated with calcium phosphate. That would agree with my conception of the action of the parathyroid hormone. It is my belief that the blood calcium is low in hypoparathyroidism because the blood phosphate is high. This concept, of course, implies a tendency to supersaturation. In hyperparathyroidism, on the contrary, it is my belief that the blood calcium is high because the phosphate is low. This concept implies hyposaturation. If these concepts are correct and a supersaturation in hypoparathyroidism does exist, there should be a tendency for calcium to be deposited in abnormal places. Therefore I should like to think that these changes are due to supersaturation rather than to the colloid formation.

DR. PETER BASSOE, Chicago: As I see it there are four problems involved in this presentation: the mechanism of calcification, the effect of such calcification on the function of the brain, the question of the significance of the symmetry and the question of the role of the parathyroid. Cerebral calcification is of a kind which has aptly been called "endarteritis calcificans cerebri." The calcification is preceded by a colloid or hyaline degeneration of arterioles and capillaries. This in turn is thought to be preceded by vascular narrowing from toxic or other causes, with resulting oxygen deficiency. Kaufmann showed experimentally that arterial calcification may set in three days after carbon monoxide poisoning. In most cases previously reported only one side of the brain has been affected. By far the commonest clinical picture is that of epilepsy, called "cerebral calcification epilepsy" by Penfield. Sometimes brain tumor is simulated, as in a case described by Hassin and myself in the *Archives of Neurology and Psychiatry* in 1921. The histologic appearances are identical with those described by Drs. Eaton, Camp and Love in the May issue of the *Archives of Neurology and Psychiatry*. Our patient began having right-sided convulsions at the age of 30 years and later developed some aphasia, right-sided weakness and changes in reflexes which led to a diagnosis of brain tumor. Three operations were performed and each time a hard mass was felt so deep down that removal was impossible. The hemiplegia gradually became more complete; the patient failed mentally and died eleven years after the onset and four years after the last operation. Necropsy revealed a large calcified area in the left hemisphere, involving the basal ganglions and centrum semi-

ovale. Neither in this case nor in most others in the literature are data offered from which conclusions might be drawn as to the parathyroid function. All I can say is that in the calcifying endarteritis the process appears to be the same whether unilateral or bilateral. [The histologic changes in this case were demonstrated by five lantern slides.]

DR. CYRIL M. MACBRYDE, St. Louis: My impression that this new sterol derivative is the best thing available at present in the treatment of tetany is being borne out in a larger number of cases. At present I have twelve cases of hypoparathyroidism under control. They are chronic tetany cases, all of them treated with dihydrotachysterol and small doses of calcium by mouth. Nine of these followed thyroid operations, one followed removal of a parathyroid tumor and two of them were idiopathic cases. Two of these patients, one the idiopathic patient and one having hypoparathyroidism following thyroid operation, had epileptiform convulsions over a number of years before treatment with dihydrotachysterol. I went back over our roentgenograms to see whether I could observe any calcification, and I cannot see in these two cases any evidence of cerebral calcification in the roentgenograms. Both of these patients had signs of increased intracranial pressure, with definite papilledema. In one the spinal fluid pressure was measured and found to be over twice normal. All of these signs disappeared after proper treatment with dihydrotachysterol. The papilledema and convulsive attacks in these two patients disappeared and never returned. I want to comment about one observation shown on a slide here today. I wonder whether perhaps the authors didn't expect too much of too small a dose of dihydrotachysterol. As I remember, one patient was given 8 cc. over a period of seven days and there was no marked change in the blood calcium. I have found that it takes more dihydrotachysterol than that and a longer period of time to get a definite effect. There is a lag in the effect. I ordinarily give a new patient from 14 to 20 cc. in the first week, and a maximum blood calcium rise usually doesn't occur until about ten days after starting the dihydrotachysterol. As soon as the blood calcium begins to approach normal one should reduce the dose to 0.5 or 0.3 cc. a day. The maintenance dose is between 1 cc. and 0.3 cc. a day. I have found with the use of dihydrotachysterol that very large doses of calcium are absolutely unnecessary. Twenty grams or more daily of a calcium salt usually makes a patient uncomfortable. I find that patients are usually nauseated and have various gastrointestinal upsets with large doses of calcium. Usually 10 Gm. of calcium lactate a day, with from 0.3 to 1 cc. a day of the dihydrotachysterol is enough for a maintenance dose and will keep the blood calcium at a normal level indefinitely. The advantages of this drug, I think, are considerable. Dihydrotachysterol certainly raises the blood calcium better than vitamin D. It seems to reduce blood phosphorus better than vitamin D preparations, and it has a much more prolonged action than parathyroid injections, which must be repeated at least every twenty-four hours.

DR. SAMUEL F. HAINES, Rochester, Minn.: We agree with Dr. Albright and Dr. MacBryde that dihydrotachysterol offers the simplest treatment for the patient in case of parathyroid tetany. Although we still feel we can control tetany in the majority of the cases by the administration of large doses of calcium lactate dissolved in hot water and of some form of vitamin D, it is still easier to control it when dihydrotachysterol is used in small doses. In some cases in which diarrhea followed administration of calcium lactate we have found we have been able to control the diarrhea by the administration of dilute hydrochloric acid. In some of those cases we have found achlorhydria present. The case presented here was the first case in which we used dihydrotachysterol and the small dose was used because we were feeling our way. We know now, from further experience, that larger doses are necessary, as Dr. MacBryde has noted. It is of interest that since these cases have been observed we have taken roentgenograms of the skulls of several patients with severe chronic parathyroid insufficiency and have not found abnormal deposits of calcium.

DR. L. MCKENDREE EATON, Rochester, Minn.: There are many controversial points concerning symmetrical cerebral calcification which we could not discuss because of limited time.

It has been suggested that the cerebral changes were the cause of the convulsive seizures and mental dulling. Our experience leads us to a different opinion. Roentgenograms of the skull of the first patient made after eighteen months of treatment and relief from symptoms showed no change in the density or extent of the calcium deposits in the brain. Therefore the calcium deposits per se cannot have produced the symptoms. The latter must have been due to the disturbed calcium metabolism. Dr. Bassoe suggested that the symmetry of the lesions might not be important since a similar histologic change had been found distributed asymmetrically in the brain in other cases. However, I wonder whether the symmetrical lesions are not the result of generalized metabolic disturbances while the localized asymmetrical lesions represent a localized disease process primary in the brain.

Clinical Notes, Suggestions and New Instruments

BACILLARY DYSENTERY RESULTING FROM AN ACCIDENTAL LABORATORY INFECTION

ORAM C. WOOLPERT, M.D.; HOMER F. MARSH, M.S., AND
OWEN F. YAW, M.D., COLUMBUS, OHIO

Although dysentery due to *Shigella dysenteriae* (Shiga) has been diagnosed specifically since Shiga's¹ identification of the etiologic agent in 1897 and the disease is encountered not infrequently the world over, we have been unable to find any record of an accidental laboratory infection caused by this organism. Lippincott² recorded a mild case of Flexner's dysentery in a technician who had accidentally drawn a suspension of *Shigella paradysenteriae* (Flexner) into her mouth while doing an agglutination test on a recently isolated strain.

Shiga dysentery is ordinarily transmitted by means of contaminated food or water; it occurs sporadically or in small epidemics, as among army populations; the primary source of the bacteria is commonly a carrier or an active case. The case reported here is deemed of interest not simply because it resulted from a laboratory infection but particularly because of the unusual opportunity afforded us to work out the epidemiology and bacteriology in association with the clinical studies. In short, it presents many of the features of a well controlled laboratory experiment in which man was the unfortunate experimental animal.

REPORT OF CASE

F. G., a white man aged 23, a graduate student in the Department of Bacteriology, was seen by Dr. James C. Vanneter of the university staff Dec. 3, 1938, and was admitted late that day to the medical service of University Hospital with the clinical picture of acute dysentery. He was transferred to the isolation service the next day.

The patient was a native and resident of Brooklyn but had lived in Columbus during the autumn quarter of the school year. The past history was uneventful. He had enjoyed good health and was not subject to gastrointestinal disturbances.

On the afternoon of November 30 he was injecting a rabbit intravenously with a living suspension of *Shigella dysenteriae* (Shiga) for purposes of immunization. He had difficulty in getting the needle into the ear vein and while exerting pressure on the plunger of the syringe he inadvertently withdrew the needle sufficiently to expose the tip, consequently spraying some of the suspension of bacteria into his own face. He was aware of getting some of the material into his eyes but did not think that any was introduced directly into his mouth. He immediately washed his face and hands well in tap water but used no soap or disinfectant. The accident was not reported at the time to any member of the departmental teaching staff.

From the Departments of Bacteriology and Medicine (Isolation Service), the Ohio State University College of Medicine.

1. Shiga, Kiyoshi: Ueber den Erreger der Dysenterie in Japan, *Centrallbl. Bakt.*, 1 Abt. 23: 599 (April) 1898.
2. Lippincott, L. S.: A Case of Bacillary Dysentery Contracted in the Laboratory, *J. A. M. A.* 85: 901 (Sept. 19) 1925.

This was to have been the last inoculation given the rabbit, so the student did no further work with the animal or the *Shigella* organisms. Almost exactly forty-eight hours after the laboratory accident he suffered an acute onset of diarrhea, accompanied by abdominal pains, headache, general malaise and what he thought was a slight fever.

On admission the temperature was 100.8 F., the pulse rate was 102 and the respiratory rate was 24. The patient was well developed and well nourished. He appeared very weak and somewhat dehydrated. There was a generalized spasm of abdominal pain with tenderness and moderate rigidity in the left lower quadrant. Stools were so frequent that the patient could hardly be kept off the bed pan long enough for an examination.

The stools were watery and appeared to consist of blood-streaked pus and mucus, without fecal material. Microscopic examination of the stools confirmed the presence of pus and blood and failed to reveal any amebas. There were from 50 to 75 leukocytes, mostly polymorphonuclear, and from 2 to 5 erythrocytes per high power field. The blood count was red blood cells 7,000,000, hemoglobin 112 per cent (Sahli), white blood cells 11,050, polymorphonuclear leukocytes 65 per cent with 36 per cent adult and 29 per cent juvenile forms, lymphocytes 30 per cent, monocytes 5 per cent. The urine was acid in reaction and contained an occasional white blood cell and a few granular casts.

On the basis of a history of exposure and the presenting symptoms and examinations, a tentative diagnosis of Shiga bacillary dysentery was made.

Specific treatment was instituted as soon as possible by the administration of 100 cc. of polyvalent bacillary dysentery antiserum on the day following admission. Preliminary desensitization proved to be necessary, and for this reason the serum was given intramuscularly. Two days later an additional 100 cc. of serum from a different biological house was obtained. Again the patient appeared sensitive by cutaneous test, but most of the serum was given intravenously after desensitization.

For the first few days morphine sulfate one-fourth grain (0.015 Gm.) was given frequently to control pain; later codeine was substituted. Other treatment consisted of atropine sulfate 1/150 grain (0.0004 Gm.) as needed to allay abdominal cramps; saturated solution of sodium sulfate 6 cc. by mouth, at first every two hours, later at four, six and then twelve hour intervals, and sodium bicarbonate 15 grains (1 Gm.) every four hours until the urine was rendered alkaline. On admission the patient was given a 700 cc. sodium bicarbonate enema. Later during convalescence an enema containing 1 grain (0.06 Gm.) of potassium permanganate in 500 cc. of 0.85 per cent solution of sodium chloride was used once or twice daily. Fortunately the patient was able to take large amounts of fluids by mouth, often 5,000 cc. or more daily, so that the intravenous administration of fluids became unnecessary. A moderate serum sickness which developed was treated in the usual manner.

The course of the disease was one of gradual improvement. The temperature, which reached 103.2 F. on the second hospital day, probably augmented by a reaction to the serum given, fell to normal by the tenth day. The stools continued to be very frequent for about two weeks, at the end of which time fecal matter first began to appear. The blood erythrocytes fell to a low of 3,510,000 by the fifth day as body fluids were restored and slowly rose to almost 5,000,000 when the patient was discharged on the twenty-fifth hospital day. The blood leukocytes correspondingly fell to approximately 7,000 and remained near that level.

BACTERIOLOGY

History of Infecting Strain.—The history of the organism with which the patient worked is of particular interest because it relates his infection to a recent outbreak of severe dysentery.

During the summer of 1938 an epidemic of bacillary dysentery occurred in the neighborhood of Owosso, Mich., involving approximately 150 cases, of which not less than fifty were severe. Of seven fatalities, all were among children. *Shigella paradysenteriae* (Sonne) was isolated from some of the patients, but *Shigella dysenteriae* (Shiga) was proved to be the responsible agent in sixteen cases, including four that were fatal.

One of us (H. F. M.), engaged in research in intestinal bacteriology, requested through the Michigan Department of Health several cultures of the *Shigella* organism isolated in the Michigan epidemic. Four cultures were kindly supplied.³ One of these cultures (derived from a non-fatal case) was being used by the student at the time of his accident. The culture was not more than three months removed from the human case; it had been in semisolid agar for approximately two months of that time and had been transferred altogether about twelve times since primary isolation.

Isolation and Identification of Patient's Strain.—On the first day of hospitalization a stool specimen was streaked out on two eosin-methylene blue plates and two Endo-agar plates. At the end of a twenty-four hour incubation period, the plates showed an almost pure culture of a non-lactose fermenting organism which appeared as a gram negative rod on staining. Cultures were made from these plates into plain broth and into Russell's double sugar agar slants. At the end of six hours' incubation there was sufficient growth to carry out a motility test; this showed that the bacteria were non-motile. As soon as the growth was sufficient in the Russell slants it was seen that the organism produced acid only in the butt of the tube, with no change on the slope. These reactions placed it in the *Shigella* genus.

From the broth cultures transfers were made to the following mediums: lactose, dextrose, sucrose, mannite, levulose, raffinose, xylose, dulcitol and rhamnose broth; tryptophan broth; nitrate broth; Koser-Simmond's citrate agar slants; litmus milk, and gelatin.

The broths were observed at twenty-four and forty-eight hours, and the following changes were recorded: acid without gas in dextrose, levulose and raffinose, and no change in the other carbohydrates; no growth on the citrate agar; a slight production of acid in the milk, changing to a neutral reaction, and finally to a very slightly alkaline reaction. The tests for indole and the reduction of nitrates were negative at forty-eight and ninety-six hours. Gelatin was not liquefied in two weeks.

These cultural changes are those characteristic of *Shigella dysenteriae* (Shiga).

Since the first plate cultures of the patient's stool were apparently almost pure and we had in mind the strong possibility of *Shigella dysenteriae* (Shiga) infection, it was thought worth while to attempt serologic identification of the patient's strain by using, as an antigen, the growth taken directly from one of the original Endo plates. For the test antiserum, we had at our disposal the antiserum which the student had been preparing in rabbits. Not only, then, did this serum represent a known antiserum for *Shigella dysenteriae* (Shiga) but also it had been prepared against the very strain of these organisms to which the patient had been exposed. Appropriate agglutination tests were set up, therefore, the patient's culture and a stock culture of *Shigella paradysenteriae* (Flexner) being used against the rabbit serum. The tubes were incubated for an hour and a half at 45 C. (113 F.) at the end of which time agglutination was found to be complete to a titer of 1:320 in the tubes containing the patient's strain, whereas there was no agglutination of the Flexner strain. The tubes were refrigerated overnight and on rereading the patient's strain was seen to be agglutinated to a titer of 1:1,280, with no agglutination of the Flexner organism. Thus a presumptive serologic identification of the recovered strain was established within twenty-four hours. Later agglutination tests with pure cultures of the patient's strain confirmed the earlier serologic and cultural reactions, identifying the organism as *Shigella dysenteriae* (Shiga).

On the tenth day of hospitalization another stool culture was made as before. Again the plates revealed an almost pure culture of a non-lactose fermenting bacterium which was identified as *Shigella dysenteriae* (Shiga).

Stool cultures were positive again on the twentieth day, but at this time only about half of the colonies were *Shigella*. No *Shigella* organisms could be recovered from cultures taken

3. Dr. C. C. Young, director, Mr. W. W. Ferguson, senior bacteriologist, and Dr. F. C. Forsbeck, epidemiologist of the Michigan State Department of Health, supplied these cultures as well as salient information concerning the Michigan outbreak.

on the twenty-fourth day, and two cultures taken subsequent to the patient's release from the hospital were likewise negative.

SEROLOGIC STUDIES

Specimens of the patient's serum were obtained on the third and nineteenth days of hospitalization and on the tenth day after his discharge, or thirty-five days after the onset of illness. These were set up for agglutination tests against the following organisms: a culture from the patient, the original culture of *Shigella dysenteriae* (Shiga) given him for his work, a department stock culture of the same organism and a stock culture of *Shigella paradysenteriae* (Flexner). The results of these tests were as follows: There was no agglutination of the Flexner organism in any of the serums; there was no agglutination of the other cultures run against the first and second specimens of the patient's serum; agglutination was complete at 1:80 and partial at 1:160 in the tubes containing the third serum specimen run against the patient's strain, as well as the experimental culture used by the patient and the stock strain of *Shigella dysenteriae* (Shiga). It is evident, therefore, that the patient originally had no agglutinins for the *Shigella* organisms but that a specific serologic immunity developed during the course of his infection.

COMMENT

When we first saw this student we were hesitant to ascribe his infection to laboratory exposure. We had never heard of a laboratory infection due to *Shigella dysenteriae* (Shiga) and we erroneously assumed that he had been working with an old stock culture of low virulence. On the basis of the evidence presented, however, we feel that there can be no reasonable doubt concerning the source of the infecting organism. It is significant that the strain had been isolated only three months earlier from an epidemic having a high fatality rate and that it had been passed through only a few transfers on artificial mediums. It cannot be said with certainty whether the student got some of the bacteria directly into his mouth, whether they gained access through the nasal passages or whether they were carried into his mouth from the lips or hands when he ate dinner shortly after the accident. In any case, infection must have been closely associated with the laboratory episode since he did no further work with these bacteria. It is pertinent to note also that the student took all his meals at a restaurant which is well attended by university people and that no other cases of dysentery were reported.

The incubation period of forty-eight hours is compatible with the range usually given of from one to three days.

The antibody response represented by an agglutinin titer of 1:80 is of the order reported for infections due to the Shiga dysentery bacillus. It is of interest that, although the patient was given 200 cc. of polyvalent dysentery antiserum, there was no immediate effect on his titer of serum agglutinins as a result of this passive immunization. Since by actual test we found the agglutinin titer of the commercial serum to be very low, this fact is understandable. It is evident that the agglutinins later demonstrable in the patient's serum must have been developed actively in his own body.

SUMMARY

1. A case of bacillary dysentery due to *Shigella dysenteriae* (Shiga) resulted from accidental laboratory infection. So far as we have been able to learn, no similar case has been recorded previously.

2. The infecting strain had been recently isolated from an epidemic having an unusually high case fatality rate.

3. Following a definitely determinable exposure, the incubation period in the instance reported was forty-eight hours.

4. A specific laboratory diagnosis was established within twenty-four hours. The careful bacteriologic and serologic studies carried out prove that the strain of Shiga dysentery bacillus recovered from the patient was identical with the laboratory strain to which he was exposed.

5. Although *Shigella dysenteriae* (Shiga) is universally accepted, on the basis of ample evidence, as the specific etiologic agent for one type of bacillary dysentery, we believe that the data presented here afford an interesting confirmation of that relationship.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

BURDICK QA-250 ULTRAVIOLET LAMP ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick QA-250 Ultraviolet Lamp is the hot cathode, mercury quartz type, recommended for use only by the physician or under his direction by prescription. The base supports a control unit containing the transformer, relay and other electrical parts for starting and operating the burner. An aluminum reflector at the top of the stand concentrates the radiation from a burner to an area approximately 6 feet long and 2 feet wide.

The reflector may be adjusted from heights of about 40 to 70 inches and turned in various angles in the horizontal or vertical axes. The lamp must be connected to a 25 or 60 cycle alternating current and requires an input of 250 watts.

The burner is air cooled and operates at a high vapor pressure and relatively high temperature. At a distance of 30 inches from the burner a first degree erythema may be produced on the average skin within two minutes.

The firm submitted a report from a dependable laboratory giving information on the lamps with regard to (a) the total radiation from the lamps, (b) the spectral distribution of energy in the ultraviolet (and visible) region and (c) the divi-

Fig. 1.—Burdick QA-250 Ultraviolet Lamp.

Fig. 2.—Spectral energy distribution.

sion of total energy among the three regions ultraviolet, visible and infra-red. In making the tests for the total radiation, the mercury lamp was mounted with the tube vertical, the axis of

Radiation in Individual Lines

Wavelength, Angstroms	Microwatts per Square Centimeter at 30 Inches
2,399	44
2,483	84
2,536	176
2,652	181
2,803	99
2,894	57
3,022	264
3,132	462
3,342	70
3,650, 54, 62	770
4,047	233
4,358	387
5,461 (5,770-5,790)	704
10,140 (others nearby)	348

the tube 30 inches from the receiving surfaces, and the line from the receivers to the center of the tube perpendicular to the rim of the reflecting shield. In measuring the range of the ultraviolet spectrum, a Leiss quartz spectrometer was used.

The distribution of energy in the three general regions (ultraviolet, visible and infra-red) was found to be as follows: In the visible the important lines are at wavelengths 4,358,

5,461 and 5,770-5,790. The yellow and green together gave radiation at 934 microwatts per square centimeter, the deep blue at 501. Therefore, in the visible spectrum the lamp radiates at 1,435 microwatts per square centimeter in the ultra-violet (including the line at 4,047) at 2,800, and in the infra-red (including the lines at and near 10,140 angstroms, which themselves amount to 400 units) 7,900 microwatts per square centimeter. Of this 7,900 units, about 7,500 is beyond 14,000 angstroms and represents the thermal radiation of the hot quartz. The results are all summarized in the accompanying table and in figure 2.

The unit was submitted by the Council to a qualified physician for clinical usage, and he reported that it functioned adequately.

On the basis of the evidence provided in the foregoing report, the Council on Physical Therapy voted to accept the Burdick QA-250 Ultraviolet Lamp for inclusion in the Council's list of accepted devices.

ALOE UTILITY SHORT WAVE UNIT ACCEPTABLE

Manufacturer: A. S. Aloe Company, 1819 Olive Street, St. Louis.

The Aloe Utility Short Wave Unit is recommended for medical and minor surgical diathermy. It is a semiportable model with an available cabinet or chrome stand to serve as a base. Condenser pad electrodes and an induction coil are standard accessories. Cuff electrodes, surgical instruments and a foot switch are optional equipment.

Aloe Utility Short Wave Unit.

Providing a 12 meter wavelength, the unit utilizes two tubes in a self-rectifying, push-pull, tuned plate, tuned grid oscillating circuit. The output circuit, inductively coupled to the plate circuit, is controlled by a variable air condenser in series with one patient terminal.

The Aloe Utility Unit was examined under the auspices of the Council. It was operated for two hours under a full output load of 160 watts (measured by lamp load and photoelectric cell).

Schematic diagram of circuit.

The final transformer temperature was within the limits of safety. The power required to operate the machine was approximately 550 watts and the electromotive force across the line was 116 volts. Evidence was submitted by the firm concerning the deep heat produced by the unit within the body tissues. Tests were run with cuff and coil techniques. A stiff resilient metal was used in the cuffs so that they embraced the thigh with a springlike action. These were $2\frac{3}{8}$ by 25 inches (upper cuff) and $2\frac{3}{8}$ by $18\frac{1}{2}$ inches (lower cuff). The metal strip in the electrodes was approximately $1\frac{1}{2}$ inches wide. The average distance between the cuffs was $6\frac{1}{2}$ inches (right) and $6\frac{1}{3}$ inches (left). The average spacing was five-eighths inch (right) and three-fourths inch (left). The room temperature was about 72 F. and the humidity about 54 per cent. All applications were given for twenty minutes and the power was applied up to the patient's heat tolerance.

When the inductance coil tests were run, there was a distance between the coils of about 1 inch and the coil was separated from the skin by about one-fourth inch spacing. The average thigh circumference was approximately $20\frac{1}{2}$ inches. The room temperature stayed around 69.5 F. while the humidity was approximately 54 per cent.

Average Temperatures (F.) of Six Observations, Cuff Technique

Deep Muscle		Rectal	
Initial	Final	Initial	Final
98.2	105.8	99.6	99.5

Average Temperatures (F.) of Six Observations, Coil Technique

Deep Muscle		Rectal	
Initial	Final	Initial	Final
96.4	105.6	98.7	98.9

The unit was put on trial in a clinic acceptable to the Council and it was reported to give satisfactory clinical service.

In view of the foregoing report, the Council on Physical Therapy voted to include the Aloe Utility Short Wave Unit in the Council's list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

CHORIONIC GONADOTROPIN

The numerous names which have been given to the gonadotropic substance excreted in the urine of pregnant women have led to considerable confusion and ambiguity for many years. The Council considered it advisable, therefore, to adopt a term which would describe the origin and action of this substance and thus avoid the use of misleading names.

When it was discovered by Zondek and Aschheim in 1928 that the urine of pregnant women contained a gonadotropic substance, it was thought that this substance was elaborated by the anterior lobe of the pituitary. The names by which this substance were then designated reflected this view, e. g. prolan, antuitrin, antophysin, praehormon. Several years later it was conclusively demonstrated that the gonadotropic action of pregnancy urine differed significantly from that of the anterior lobe in certain physiologic responses. From this time investigators have commonly referred to this urinary gonadotrope as the anterior pituitary-like substance. Other names by which this substance is known are P. U., A. P. L., pregnancy urine hormone and prolan B. Fluhmann suggested in 1934, on the basis of his studies and those of others, the name "chorionic ovary-stimulating hormone," since it was definitely shown that this substance was elaborated by chorionic tissue, such as the placenta, hydatid mole, chorio-epithelioma and certain embryonal teratomas.

In 1937 the Council voted to adopt as the designation of this substance the term "chorionic gonadotropin," which signifies its origin from chorionic tissue and its gonadotropic action. This action was not published at that time. At the League of Nations Third International Conference on the Standardization of Hormones in 1938 it was agreed to adopt "the term 'gonadotrop(h)in' for reference to principles with gonadotrophic action, with the addition, in each case, of a suitable adjective or descriptive phrase, to indicate the source of origin of the particular principle to which reference is made." This is in close agreement with the action of the Council, and it appears, therefore, that the term "chorionic gonadotropin" is an international one. It is hoped that the use of this term will soon displace that of the various other names which have been attached to the substance.

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

THIRTY-NINTH ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

In its 1939 compilation of educational data, the Council on Medical Education and Hospitals has endeavored to present in statistical form or editorial comment facts regarding its major activities. Information regarding the approved undergraduate medical schools for the academic year 1938-1939 is given in the customary manner, including a tabulation of the number of citizens of the United States enrolled in faculties of medicine abroad. The second and more detailed report on extension courses for practicing physicians appears in this issue. The requirements and personnel of approved examining boards in specialties is an added feature this year. Also included are revised lists of hospitals approved by the Council for internships and residencies and fellowships. The Essentials for Approved Examining Boards in Specialties and the Essentials of Approved Residencies and Fellowships are reprinted as recently revised. Reproduced also are some of the other Essentials promulgated by the Council, namely the Essentials of an Acceptable Medical School and the Essentials in a Hospital Approved for Training Interns.

The Council in February 1937 adopted a resolution that, effective July 1, 1939, it would publish separately a list of schools which teach only the basic medical sciences. They so appear in this issue and the statistics therefor cover sixty-seven approved medical schools¹ in the United States and nine in Canada, and ten² recognized schools of the basic medical sciences in the United States and one in Canada. Included also are 734 hospitals approved for internships and 518 hospitals offering approved residencies and fellowships in specialties.

The factual study of extension courses for practitioners covers thirty-six states and the District of Columbia visited since October 1937 and brings up to date the preliminary report presented last year.³

All these data are based on official reports. Acknowledgment is extended to the officials of the institutions and agencies named and others for their cordial cooperation in supplying the material submitted in this presentation and for other data furnished throughout the year to the office of the Council and the members of its staff on inspection or visitation, enabling the Council to maintain its medical student and hospital registers efficiently and to carry on its activities as outlined by the House of Delegates of the American Medical Association.

PRELIMINARY EDUCATION

Although many schools have additional requirements, the following statement indicates the minimum of preliminary education which is acceptable to the Council:

The minimum requirement for admission to approved medical schools is two years of college training which include English, theoretical and practical courses in physics, biology and general and organic chemistry. Three years or more in college is, however, recommended.

Since it cannot in general be assumed that all who have satisfied these requirements merely in terms of hourly credits are

fitted for the study of medicine, it is desirable that qualitative standards for admission should be imposed.

As a rule candidates should have received their preliminary education in institutions approved by accrediting agencies acceptable to the Council. Exception to this rule may be made in the case of applicants who have demonstrated superior ability. For the convenience of admitting officers the Council has prepared a list of colleges of arts and sciences approved by national and regional educational associations.

Admission to approved medical schools may also be by examination under the following conditions:

(a) Candidates who have completed two years of collegiate instruction and present evidence of general scholarship of high order, but who lack credits in not more than two of the required subjects, may be admitted on passing examinations in these subjects.

(b) Candidates who have completed three years of collegiate instruction and present evidence of having accomplished work of distinction in one or more fields of learning, but who lack credit in any or all of the required subjects, may be admitted on passing examinations in these subjects.

TABLE 1.—Preliminary Requirements

Requirement	No. of Schools	
	1938-1939	1939-1940
Degree	5	5
Years		
Four	1	1
Three*	5	5
Three	45	55
Two and one-half	2	..
Two	19	11
Totals	77	77

* Baccalaureate degree conferred in absentia at end of first medical year.

The standardizing agencies acceptable to the Council are:

Association of American Universities.
North Central Association of Colleges and Secondary Schools.
Middle States Association of Colleges and Secondary Schools.
New England Association of Colleges and Secondary Schools.
Southern Association of Colleges and Secondary Schools.
Northwest Association of Secondary and Higher Schools.

For the year 1938-1939 the Council's compilation of colleges of arts and sciences approved by these bodies numbered 791, distributed as follows:

Association of American Universities	269
North Central	284
Southern	238
Middle States	134
Northwest	69
New England	49

Of those recognized by the Association of American Universities, all but seventeen are approved also by their district agency. In the various groups this dual approval of 269 institutions is distributed as indicated below:

North Central	101
Southern	58
Middle States	44
New England	31
Northwest	18

The five regional associations of colleges referred to cover among them the entire United States with the

(Continued on page 760)

1. Includes one school on probation. See footnote to table 2, page 759.
2. Includes two on probation. See footnotes to table 3, page 760.

exception of the far Southwest. Institutions in this territory can secure only the approval of the national group—the Association of American Universities.

While the minimum requirement of the Council for approved schools is two years, three years or more in college is recommended. For the session 1939-1940, sixty-six of the seventy-seven medical schools in the United States, including the ten schools of the basic medical sciences, had a premedical prerequisite in excess of the minimum. For the session 1938-1939, fifty-eight required more than two years. In table 1 is tabulated for both sessions the number of schools requiring a degree, four years, three years if the baccalaureate degree is conferred in absentia at the end of the first year in medicine, three years, two and one-half years and two years.

ing one school offering courses in the basic medical sciences, require two years, and one has a three year prerequisite.

A table appears later in this study which records the number of graduates of 1939 holding baccalaureate degrees (table 16). The premedical training required by the medical licensing boards in each state is shown in table 4. The two year minimum has been one of the essentials of an acceptable medical school since 1918. Yet five states have not revised or amended their statutes to conform with these prerequisites, although with one exception these states do not as a rule license other than graduates of approved schools.

ESSENTIALS OF AN ACCEPTABLE MEDICAL SCHOOL
The Essentials of an Acceptable Medical School were revised and ratified by the House of Delegates at its

* On probation since May 13, 1939.

Only eleven schools had a stated two year requirement and ten others will demand three years for the session 1939-1940, namely the Universities of Kansas, Tulane, Minnesota, Long Island, Duke, Oklahoma, Hahnemann, Baylor, Vermont and Virginia. Most students, however, enter with a training far in excess of the prescribed minimum. The general trend toward three or more years of college work would appear to be due to a desire for more thorough grounding in all the branches of chemistry and greater familiarity with non-science subjects, such as literature, history or economics, than can be secured in two years of college. Actually, only 3.8 per cent of the freshman class of 1938-1939 were admitted with less than three years.

The medical schools in Canada vary in their preliminary requirement. For the session 1939-1940 one requires a degree for admission to a five year course; four have a six year medical course preceded by senior matriculation which is equivalent to the work of the first year in a college of arts; one school requires one year for entrance to a five year medical course; three, includ-

1938 session. They are published on pages 790 to 792. The principal change was the recommendation that medical schools not already doing so select their students from among those having three years of college work rather than the minimum requirement of two years. This recommendation was based on a study which revealed that more than one half of the students admitted (3,181) for the session 1936-1937 had a college degree before beginning medicine and 32 per cent had more than four years, leaving only 12 per cent with the minimum of two years. Seven schools raised their requirement for the session 1938-1939 and ten for the session 1939-1940, leaving only eleven schools with a stated two year requirement.

The preliminary requirement for admission to the medical schools in twenty-one schools for the session 1938-1939 was the minimum—two years. A study of the premedical work completed by the students admitted to these schools reveals that only 223, or 3.8 per cent, of the total freshmen enrolment were accepted on the minimum basis. Similar figures computed on the basis

of the freshman class of 1936-1937 placed 12 per cent in this class or 716 students. Ten of the twenty-one schools referred to have raised their requirement for the session 1939-1940. A further study reveals that two of the twenty-one schools did not admit any one with the minimum prescribed preparation, while, on the other hand, one school accepted thirty-five and another thirty-seven, the highest figure.

LENGTH OF MEDICAL COURSE

The medical course in the United States in general covers four academic years of approximately thirty-two weeks each. Fifty-one schools offer such a course. The medical schools of the Universities of Northwestern, Minnesota, Duke and Tennessee operate on the quarter system, permitting a student by utilizing the summer months to decrease the length of time necessary to obtain his degree. A considerable number of the students of these schools do not elect to study during the summer months. The medical schools of the University of Chicago are operated on a plan of individual promotion permitting a student to advance as rapidly as he desires, but the great majority complete the course in twelve quarters.

TABLE 4.—State Requirements of Preliminary Training

Two Years of College		
Alabama	Maine	Oregon
Arizona	Maryland	Pennsylvania
Arkansas	Michigan	Rhode Island
Colorado	Minnesota	South Carolina
Delaware	Mississippi	South Dakota
District of Columbia	Montana	Tennessee
Florida	Nevada	Texas
Georgia	New Hampshire	Utah
Idaho	New Jersey	Vermont
Illinois	New Mexico	Virginia
Indiana	New York	Washington
Iowa	North Carolina	West Virginia
Kansas	North Dakota	Wisconsin
Kentucky	Ohio	Wyoming
Louisiana	Oklahoma	
One Year of College		
California	Connecticut	
High School Graduation or Its Equivalent		
Massachusetts	Missouri	Nebraska

Fifty-five schools require a four year course, while twelve require four years of systematic instruction followed by a fifth year spent as an intern or in research work. Ten schools offer only a two year course. Five of the medical schools of Canada offer a five year course, four have a six year course and one offers courses in the medical sciences only which are covered in two years. Four Canadian schools require an internship for graduation. These data are shown in tables 2 and 3.

MEDICAL SCHOOL SURVEY

In September 1933 the Council on Medical Education and Hospitals voted to undertake a resurvey of all medical schools in the United States and Canada. During the academic years 1934-1935 and 1935-1936 Dr. Herman G. Weiskotten, dean of Syracuse University College of Medicine, visited all schools in company with a representative of the Council, the Association of American Medical Colleges or the Federation of State Medical Boards of the United States. A confidential report in graphic form by which the schools were grouped in tenths of a rank order of excellence for each one of several criteria was sent to the schools visited. A committee of the Council is now preparing a final report which it is expected will present a comprehensive

review of medical education in this country. Such a commentary will doubtless be a valuable source of information to all who may be interested in medical teaching and will constitute a permanent record of the Association's most important contribution in the field of professional education. This book will be available during the early part of the next college session.

DEVELOPMENTS IN MEDICAL EDUCATION

Reports received from a large number of medical schools and follow-up inspections of many indicate that, as a result of the Council's survey, substantial improve-

TABLE 5.—Improvements in Medical Schools 1934-1939

Study of Twenty-Eight Lower Ranking Medical Schools	
Increased Budgets	Twenty-four schools increased annual budgets an average of \$47,192 each, totaling \$1,132,599
Selection of Students	Twenty-two schools selected students more carefully and adopted higher scholastic standards
Salaried Instructors	Twenty-five schools increased the number of salaried instructors
Preclinical Facilities	Seventeen schools improved preclinical facilities at costs of from \$29,000 to \$500,000
Clinical Facilities	Twenty schools improved clinical teaching facilities at costs totaling \$10,546,529
Other Facilities	Eleven schools have improved their libraries, building service and other facilities

ments have been and are being made. A study of twenty-eight lower ranking medical schools may be found in table 5.

MEDICAL CURRICULUM

The standard curriculum recognized by the Council on Medical Education and Hospitals and contained in its Essentials of an Acceptable Medical School consists of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours a year and grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses as stated:

	Per Cent	
1. Anatomy, including embryology and histology...	14	18.5
2. Physiology	4.5	6
3. Biochemistry	3.5	4.5
4. Pathology, bacteriology and immunology.....	10	13
5. Pharmacology	4	5
6. Hygiene and sanitation.....	3	4
7. General medicine	20	26.5
Neurology and psychiatry		
Pediatrics		
Dermatology and syphilology		
8. General surgery	13	17.5
Orthopedic surgery		
Urology		
Ophthalmology		
Otolaryngology		
Roentgenology		
9. Obstetrics and gynecology.....	4	5
Totals	76	100
Electives	24	0

When the teaching conditions demand it, a subject may be transferred from one division to another.

SCHOOLS OF THE BASIC MEDICAL SCIENCES

There are ten schools in the United States and one school in Canada which offer only the first two years of the medical curriculum. For the most part these schools are located in smaller communities where clinical material is so scarce that satisfactory teaching of clinical medicine would be utterly impossible. In many instances, facilities do not exist for the satisfactory teaching of such subjects as physical diagnosis and gross pathology, which involve the use of clinical material. The same is true of the introductory courses in medicine and surgery, which commonly form a part of the second

(Continued on page 764)

[illegible]

(Continued from page 761)

year schedule. Prolonged study of the problem led to the adoption in February 1937 of the following policy:

Following the recent survey of the medical schools it was decided that, effective July 1, 1939, the Council will publish a list of schools which teach acceptably gross and microscopic anatomy, biochemistry, physiology, pharmacology, bacteriology and pathology, even though they do not offer a full course leading to a medical degree.

The acceptance of courses involving the use of clinical material shall be left to the discretion of the faculties which admit to advanced standing students transferring from approved schools of the basic medical sciences.

Surveys of the clinical courses and facilities will be made by the Council and reported to the individual medical schools on request.

Accordingly, the educational data in tables 2 and 3 are presented in two parts:

1. *Recognized Medical Schools in the United States and Canada.*
2. *Recognized Schools of the Basic Medical Sciences in the United States and Canada.*

In subsequent tabulations, however, the figures for the two groups are combined.

APPROVAL OF MEDICAL SCHOOLS IN CANADA

On June 24, 1937, at a meeting in Ottawa, Ont., Canada, at which representatives of the medical schools in Canada and the assistant secretary of the Canadian Medical Association were present, the secretary speaking for the Council on Medical Education and Hospitals discussed the survey of Canadian medical schools made during 1934-1936 and inquired as to the policy to be adopted in the future—that is, whether the American Medical Association should continue the grading of medical schools in Canada or whether they would prefer that the medical schools themselves or some other body take over this task. The problem was referred to the Canadian Medical Association.

At its sixty-ninth annual meeting in June 1938 the Committee on Medical Education of the Canadian Medical Association brought in a report which was accepted by the members of the General Council of the Canadian Medical Association and reads, in part, as follows:

In the event of the Council on Medical Education of the American Medical Association publishing a list of approved schools, those Canadian schools wishing their inspection and approval could request this inspection. This would leave each school free to deal directly with the Council on Medical Education of the American Medical Association and thus obviate misunderstandings.

There seems to be a fairly uniform opinion expressed by the various medical schools in Canada—that the Canadian Medical Association should share some responsibility in this country so far as medical education is concerned. The majority of the schools, however, feel that the aims and purposes of the Canadian Medical Association are not primarily those of undergraduate medical education, which is largely a problem of the schools themselves. However, it is recommended that, if the Council on Medical Education of the American Medical Association in the future conduct similar surveys at five or ten year intervals, such as the recent survey, the Canadian schools take advantage of and be included in this survey. Those schools which are members of the Association of American Medical Colleges could have a representative from this association included in the personnel of the inspection. The remaining schools which are not members of the Association of American Medical Colleges could ask to have a member of the Association of American Medical Colleges included in the inspecting personnel, or some representative from the Committee on Medical Education of the Canadian Medical Association.

It would appear from the foregoing that the approval of medical schools by the Council on Medical Education and Hospitals of the American Medical Association rests with the schools themselves.

The Council on Medical Education and Hospitals at a meeting in St. Louis on May 13, 1939, voted that after Jan. 1, 1945, the Canadian medical schools will be included in the Council's classification only at their own request.

STATISTICS OF MEDICAL SCHOOLS AND SCHOOLS OF THE BASIC MEDICAL SCIENCES

Medical schools approved by the Council on Medical Education and Hospitals during 1938-1939 are listed in table 2, pages 758 and 759, which lists the premedical requirement for the session 1939-1940, the length of the medical course by years, enrolment by classes for the session 1938-1939, including fifth year students interning or engaged in research, the number of graduates since July 1, 1938, and dates of the beginning and ending of the forthcoming session and the month until which applications for admission to the freshman class are received. Changes in the classification that have taken place since the publication of the educational statistics in 1938⁴ can be noted in the footnotes at the bottom of the table and refer to those schools which are marked by asterisks preceding the name. Also contained in the footnotes are references to the fifth and sixth year enrolments and those schools which admit students at varying times during the year. The two medical schools of the University of Chicago do not report their students by classes and in this tabulation, therefore, only the total enrolment is given.

Similar data pertaining to the schools of the basic medical sciences are given in table 3.

The data presented in this table constitute the basis also for several of the subsequent tabulations, and beginning on page 825 are given historical information and essential facts concerning the schools arranged by states.

Sixty-seven medical schools in the United States and nine in Canada are listed and ten schools of the basic medical sciences in the United States and one in Canada. All but three of these schools at the present time enjoy the approval of the Council, the three being on probation. In eighty-five schools, 6,364 freshmen students were enrolled, 5,733 sophomores, 5,506 juniors, 5,447 seniors, 398 fifth year and 247 sixth year students during the session just ended. In the two medical schools of the University of Chicago 520 students were enrolled, making a total of 24,215 in the eighty-seven schools listed. There were in the United States 5,754 freshmen, 5,160 sophomores, 4,947 juniors, 4,921 seniors and the 520 students of the University of Chicago, a total of 21,302. The total students registered by classes in the United States was 22,454. The enrolment in the schools of the basic medical sciences in the United States numbered 569, of which 330 were freshmen and 239 sophomores. The enrolment in the ten Canadian schools was first year 610, second year 573, third year 559, fourth year 526, fifth year 398 and sixth year 247, a total of 2,913. In the one school of the basic medical sciences in Canada there were forty-seven students: twenty-four freshmen and twenty-three sophomores.

The 24,215 medical students enrolled exclude 1,152 fifth-year students in the United States interning or engaged in research and 121 in Canada interning as a requirement for the degree of Doctor of Medicine.

4. J. A. M. A. 111: 786 (Aug. 27) 1938.

Since July 1, 1938, 5,575 received M.D. degrees, 5,290 from schools in the United States and 285 from Canadian institutions.

There were also 117 part time, 251 special and 1,461 graduate students studying in medical schools.

With one exception the schools of the basic medical sciences had an enrolment of considerably less than 100. The lowest enrolment among regular medical schools was 100 students at the Woman's Medical College of Pennsylvania and the highest 798 at the University of Toronto Faculty of Medicine. The correspondingly high figure among schools in the United States was 638 enrolled at the University of Illinois College of Medicine.

Twelve schools, exclusive of those of the basic medical sciences, matriculated 200 or less with one exception. One school had 100 students, thirty-two between 201 and 300, fourteen from 301 to 400, twelve from 401 to 500 and three between 501 and 600. Two schools matriculated more than 600. The smallest enrolment (forty) was at Dartmouth Medical School, where twenty-two freshmen and eighteen sophomores were matriculated. This school does not offer the complete medical course. Among coeducational medical schools, Albany Medical College enrolled the smallest number of students, 112.

The Woman's Medical College of Pennsylvania likewise graduated the lowest number, twenty-one. The school granting degrees to the greatest number was the University of Illinois College of Medicine, which awarded 160 diplomas.

The majority of schools will begin the session 1939-1940 about the middle of September and complete the year's work early in June.

Of seventy-one schools that replied to the inquiry regarding the month until which applications for admission to the first year class will be received, three replied January, three February, fifteen March, five April, seven May, nine June, nine July, seven August, twelve September and one December.

The name of the dean or administrative officer of each institution is also given in tables 2 and 3.

BIRTH PLACE OF STUDENTS

In table 6, pages 762 and 763, the birth state of students in attendance in medical schools during 1938-1939 is shown by schools. The state furnishing the greatest number of students, according to state of birth, was New York with 2,863, followed by Pennsylvania with 1,849, Illinois with 1,443 and Ohio with 1,097. Fewer than 900 were born in any other one state. Six states contributed less than 100 students, the lowest being Wyoming with twenty-eight. In ten states there were between 100 and 200 students, ten less than 300 but more than 200, seven less than 400, three less than 500 and the same number between 500 and 600 students and also 700 and 800, while in one state there were between 600 and 700 and in another between 800 and 900 students.

There were 192 born in the United States territories and possessions studying in forty-six schools in the United States and two in Canada. In addition, 2,585 students of Canadian birth were also studying medicine, 136 of whom were matriculated in forty-two schools in the United States and 2,449 in the ten Canadian medical schools. Twenty students of Canadian birth were registered at the College of Medical Evangelists and thirteen at Wayne University College of Medicine. Students born in New York were enrolled in all but seven states. Pennsylvania was represented in all but twelve states.

Residents of New Jersey, which has no medical school, were admitted in all but fifteen schools. Foreign born students were matriculated in sixty-four schools. There were 515 so enrolled, of whom thirty-four were studying at the College of Medical Evangelists, thirty-three at the University of Illinois College of Medicine, twenty-one at Harvard Medical School and twenty at New York University College of Medicine. All other schools registered fewer than twenty. It may be presumed that many of these are now citizens of the United States.

From the twelve states in which no medical schools are located there were enrolled 1,791 students in at least sixty-seven schools as follows:

	Enrolled	No. of Schools
Arizona	46	23
Delaware	36	15
Florida	161	35
Idaho	99	32
Maine	112	34
Montana	129	35
Nevada	30	19
New Jersey	721	67
New Mexico	36	23
Rhode Island	115	29
Washington	278	47
Wyoming	28	17
Total	1,791	

The classification of students by birth place is extended further in table 7, indicating that 13,833 are studying in the state of their birth and 10,382 elsewhere.

TABLE 7.—Students Classified by Birth Place

	Schools	Attending School in State of Birth	Birth Place Elsewhere
Alabama.....	1	62	39
Arkansas.....	1	174	103

.....	1	30	12
.....	2	320	263
Canada.....	10	2,449	464
Totals.....	57	13,833	10,382

This is particularly significant in Illinois, where of the 2,064 students in five schools 1,010 were born outside the state. More than 900 born elsewhere are studying in Pennsylvania, while of 2,558 studying in New York only 864 were born elsewhere. Altogether, 42.9 per cent are studying in schools located in other than their birth state. Eliminating the 1,791 born in states having no medical school, there are still 8,591 of the total number of students, 24,215, studying outside their birth state.

A perusal of table 7 will show many instances wherein the number studying elsewhere far exceeds the number attending school in the state of birth. It also shows some states in which the contrary is the case, notably Arkansas, Georgia, Indiana, Iowa, Kansas, Minnesota, Ohio, South Carolina, Texas and Wisconsin.

One may not conclude that all of those attending schools in other than the state in which they were born are nonresidents; but, since requirements for residence differ widely among the schools, comparable figures based on residence are not obtainable.

RESIDENT AND NONRESIDENT STUDENTS

The number of resident and nonresident students according to each school's definition of the word "resident" is given for each medical school in the United States in table 8. Among state universities, as well as other schools, there is a variation in the definition of the term. In some universities this is determined by the legal or permanent residence of the student, parents or guardian only, while in some schools continuous residence for six months and for one, two or three years just prior to the student's application for enrolment is also required. Others require the student to be a voter, parents' home in the state established prior to beginning of premedical work, the student a taxpayer or a dependent of a taxpayer regardless of whether he resides in the state, self-supporting student, and each case determined by attorney after consideration of birth, citizenship, residence of parents, and so on. Of these methods the most common is the determination of residence by ascertaining whether the student, parents or guardian has been a bona fide resident for a period not less than six months. This requirement is in force in sixteen universities. In many schools also a student coming into the state for educational purposes only and establishing residence would not be so considered. Among other than state universities the term is defined mostly by the home address of the student or the legal residence of the parents or guardian. In one of these schools a student is considered a resident if he lives in the state.

On the basis of these factors, in the sixty-seven approved medical schools and the ten approved schools of the basic medical sciences in the United States there were 13,418 students reported as residents and 7,884 as nonresidents, a total of 21,302. The state university enrolling the greatest number of nonresidents was the University of Tennessee College of Medicine, which had 217 residents and 208 nonresidents, while at the University of Illinois College of Medicine, the University of Missouri School of Medicine, Ohio State University College of Medicine and the University of Texas School of Medicine no nonresidents were registered, and only one of the 156 students of the University of Georgia School of Medicine was a nonresident.

Among other than state universities it is of interest to note the resident and nonresident enrolment. Many of the schools select their students from residents of the state. This is particularly significant at Southern California, Stanford, Emory, Wayne, Long Island, Buffalo, Syracuse, Pittsburgh and Baylor.

The figures in table 8 giving the number of residents and nonresidents and the preceding one classifying students by birth place show a similarity. Excluding the Canadian registration given in table 7, there were 11,384 students attending school in the state of their birth and 9,918 elsewhere, as compared with 13,418 whose legal residence is in the state in which they are pursuing their medical courses and 7,884 classified as nonresidents.

The nine medical schools and the one offering courses in the basic medical sciences reported 2,284 residents of Canada and 629 nonresidents. Their definition of a resident varied from students whose permanent address is within one of the provinces of Canada or the specific province in which the school is located to home address on registration and taxpayers. The greatest number of nonresidents in any one school were found at McGill University Faculty of Medicine, where 167 of the 456 students enrolled were nonresidents. This school has always obtained a large portion of its student body from the United States. At Dalhousie University Faculty of

Medicine there were eighty-four nonresidents in a student body of 179. All other institutions registered fewer than eighty-four nonresidents but more than twenty-two with one exception—the University of Saskatchewan School of Medical Sciences—with only three nonresidents.

Comparing the figures for Canada in tables 7 and 8 reveals, as in the United States, somewhat similar figures: 2,449 born in Canada and 464 elsewhere, compared with 2,284 residents and 629 nonresidents.

SCHOOLS, STUDENTS AND GRADUATES BY STATES

Medical schools are located in thirty-six states and the District of Columbia. In table 9 are tabulated the number of schools, students and graduates by states. New York with the largest number of schools, nine, naturally had the greatest number of students and

TABLE 9.—Schools, Students and Graduates by States*

* Excluding fifth or intern year students.

graduates, 2,558 and 606 respectively; Pennsylvania with six schools had 2,314 students and 567 graduates; Illinois with five schools, 2,064 students and 586 graduates, ranks third, while Massachusetts with three schools, 1,114 students and 289 graduates and California with four schools, 1,021 students and 273 graduates complete the group of states having a medical school enrolment over 1,000.

In the seventy-seven schools, including those that offer courses in the basic medical sciences only, there were 21,302 students and 5,089 graduates. Students interning as a requirement for the degree, or fifth year students, are not included in this figure. Neither are part time, special and graduate students. The greatest number of graduates in any one state were the 606 who completed their courses in New York schools. There were 586 from Illinois schools and 567 from schools in Pennsylvania. Four other states had more than 200 graduates—California, Massachusetts, Missouri and Ohio. Eleven states had more than 100 but less than 200 graduates. All others had less than 100.

HOSPITAL INTERNSHIPS

The medical schools and licensing boards requiring a hospital internship for the M.D. degree and state licensure, respectively, are shown in tables 10 and 11. Thirteen schools in the United States and four in Canada exact the internship requisite. Several medical schools will accept research or other clinical work in

* Two year internship required.

lieu of hospital service. The University of Minnesota Medical School was the first school to require this added training. Since 1915 the M.D. degree has been conditioned on an internship. Rush Medical College, which had required the internship for the M.D. degree since 1919, and the School of Medicine of the Division of the Biological Sciences, University of Chicago, since 1930, discontinued this formal requirement in 1936. McGill University Faculty of Medicine reorganized its medical curriculum into a course of five years, including an internship replacing the former course spread over five academic years of seven and one-half months each by a course covering four years of nine months. The fifth year may be spent in an internship in an approved hospital or in further medical study at McGill or in another medical school approved by it. The changed curriculum was inaugurated for the freshman class of 1936-1937. It will not affect the students who began their course under the former system.

The M.D. degree is granted after completion of the senior year by Duke University School of Medicine, but all graduates are required to spend at least two years in hospital or laboratory work after graduation.

TABLE 11.—Internship Required by Medical Licensing Boards of All Candidates*

Alabama	Michigan	Rhode Island
Alaska	New Hampshire	South Dakota
Delaware	New Jersey	Utah
District of Columbia	North Dakota	Vermont
Idaho	Oklahoma	Washington
Illinois	Oregon	West Virginia
Iowa	Pennsylvania	Wisconsin
Louisiana	Puerto Rico	Wyoming

* Some states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants.

Twenty-one states, the District of Columbia, Alaska and Puerto Rico require that all applicants for licensure possess a hospital internship. The first state exacting this requirement was Pennsylvania in 1914. The requirement in Alabama and Louisiana became effective in 1939. In addition, other states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants.

Some of the medical schools and licensing boards have their own list of hospitals acceptable for intern training but in general follow the Council's list of hospitals approved for internships. A revised edition will be found beginning on page 832.

Total.....	22,919	1,296	5,290	285

During 1938-1939 there were 1,152 students in the United States and 121 in Canada reported as interns, a total of 1,273.

Figures computed in 1938 indicated that, with the exception of one, every medical school had more than 90 per cent of its graduates serving internships, and in fifty schools 100 per cent interned. Excluding those schools that required the internship for graduation, 98 per cent of the 1938 graduates have obtained or are obtaining this added experience.

DISTRIBUTION BY SEX

Students and graduates in the United States and Canada classified according to sex are shown in table 12. Seventy-eight schools had both men and women students, of which sixty-four had women graduates. Women were enrolled in ten of the eleven schools offering courses of the basic medical sciences. Altogether there were 22,919 men and 1,296 women students, and 5,290 men and 285 women graduates. Of these, 20,158 male students and 4,829 graduates were in schools in the United States and 2,761 and 461 respectively in Canada. Likewise there were 1,144 women students and 260 graduates in the United States and 152 students and twenty-five graduates in Canada. Of the 22,919 and 5,290 male students and graduates, 2,588 and 629 respectively were enrolled in schools in the United States which are not coeducational or do not admit women, and 282 and forty-three in Canada. An average of sixteen women students were enrolled in the seventy-eight coeducational institutions in the United States and Canada and four graduates from sixty-four colleges.

WOMEN IN MEDICINE IN THE UNITED STATES

During 1938-1939 there were 1,144 women studying medicine in the United States. The percentage of women to all students for the academic year 1938-1939 was 5.4. There were 260 graduates, twenty-three more than were graduated in 1938. Of the women matricu-

lants, 100 were in attendance at the one medical college for women, while 1,044 were matriculated in sixty-nine coeducational schools. From the Woman's Medical College of Pennsylvania twenty-one were graduated, while 239 secured their degrees from coeducational institutions. These data are referred to in table 13. Of interest also is the fact that ten schools enrolled more than twenty-five women. In the fifteen years since 1925, 3,268 women have graduated in medicine. The Council's list of hospitals approved for internships include many that offer internships open to women. Statistics

compiled on the basis of the American Medical Directory in 1938 revealed that there were 7,470 women physicians in the United States.

Women are admitted to all medical schools of the United States except the following: Georgetown, Emory, Harvard, St. Louis, Dartmouth, Hahnemann and Jefferson.

PART TIME, SPECIAL AND GRADUATE STUDENTS IN MEDICAL SCHOOLS, 1938-1939

Part time, special and graduate students in addition to the regularly enrolled students were pursuing medical subjects in forty-seven medical schools in the United States and six in Canada. This group consists of 117 part time, 251 special and 1,461 graduate students. These data are contained in table 14.

Totals	117	251	1,461

The part time students were enrolled in twenty-four schools, twenty-three in the United States and one in Canada. The largest group enrolled in any one school were twenty studying at the University of Buffalo School of Medicine. Twelve were registered in Louisiana State University and ten each at the University of Kansas and Wayne University. Less than seven were enrolled in twenty schools.

The 251 special students represented twenty-four schools in the United States and two in Canada. The greatest number (seventy-nine) were at Northwestern University School of Medicine; at the School of Medi-

cine of the Division of the Biological Sciences of the University of Chicago thirty-eight were in attendance; at the University of Kansas twenty-four, and at the University of Toronto twenty. All other schools registered fewer than fifteen.

Students pursuing subjects leading to higher degrees were studying in twenty-nine schools in the United States and five in Canada. Altogether there were 1,461, of whom more than 100 were studying in each of four schools, the greatest number (397) having been enrolled at the University of Minnesota.

The following schools matriculated these three types of students: Universities of Kansas, Johns Hopkins, Michigan, North Carolina, Oklahoma, Marquette, Toronto and New York University.

Among Canadian schools, two part time, twenty-two special and sixty-eight graduate students were enrolled.

SCHOOLS, STUDENTS AND GRADUATES IN THE UNITED STATES, 1905-1939

The number of medical schools, students and graduates for five year intervals from 1905 to 1920 and for each year since is shown in table 15. In 1905 in the

TABLE 15.—Schools, Students and Graduates in the United States—1905-1939

Year	Schools	Students*	Graduates
1905	160	26,147	5,606
1910	131	21,526	4,440
1915	96	14,891	3,536

1939	77	21,302	5,089

* Include figures for schools of the basic medical sciences

160 schools then existing there were 26,147 students. For the college session just ended there were 21,302. This tabulation includes data for only those taking medical courses leading to the M.D. degree and does not include part time and special students, though their work may later be accepted for the M.D. degree since they are not reported by medical schools as candidates for the M.D. degree. Omitted from these figures also are university graduates majoring in the medical school but not working toward an M.D. degree. As will be noted, in the ten years 1910 to 1920 there was a decrease in the enrolment of more than 7,000, while from 1921 to 1935 there was a continuous increase and since 1935 there has been a gradual decrease. In 1939 there were 285 fewer enrolled than in 1938 and 1,586 than 1935. The number of students admitted in 1938 was 977 fewer than in 1936 and 1,301 fewer than in 1935. The number of medical graduates, however, may not be decreased, since more careful selection will doubtless diminish the number of students who fail to complete their course because of poor scholarship.

Referring again to table 15, the total number of graduates in 1939 was 5,089, 105 fewer than in 1938, 112 less than in 1935 and 517 fewer than 1905. With

the exception of the slight decrease in the number of graduates in 1933 as compared with previous years, there was a steady increase from 1926 to 1937 and a decrease in 1938 and 1939.

Totals.....	5,575	3,605

In the seventy-seven medical schools in the United States, including the schools of the basic medical sciences, there were 21,302 students and 5,089 graduates.

GRADUATES WITH BACCALAUREATE DEGREES

From the figures contained in table 16 it can be noted that 3,605 of the 5,575 graduates of medical schools in the United States and Canada since July 1, 1938, also hold baccalaureate degrees while only five schools required a degree for admission. All the graduates of

Stanford, Johns Hopkins, Albany Medical College, Cornell, New York University, Western Reserve, Oregon, Jefferson Medical College, Vanderbilt, Wisconsin and Laval held baccalaureate degrees. Johns Hopkins, Albany Medical College, Jefferson Medical College and Laval University have a degree requirement. The school graduating the fewest with liberal arts degrees was Indiana University School of Medicine, where six of the eighty-six graduates also had baccalaureate degrees. One school, Queen's University, had no graduates in 1939 with arts degrees. A percentage of 64.7 of all graduates held such degrees.

STUDENTS BY YEARS, 1930-1939

The number of students enrolled in preclinical and clinical classes in the medical schools of the United States by years for each session from 1930-1931 to 1938-1939 inclusive is shown in table 17. The total attendance for the first preclinical year for the session 1938-1939 was 5,754, thirty-seven fewer than the number enrolled in 1937-1938. Since the year 1933-1934, when 6,457 were matriculated, there has been a reduction in this class of 703. The total attendance for the second preclinical year was 5,160 and for the two clinical years 4,947 and 4,921 respectively. The two

TABLE 17.—*Students in the United States by Years 1930-1939*

* Excluding enrolment figures for the two medical schools of the University of Chicago, i. e., Rush Medical College 223 and The Division of the Biological Sciences 297, a total of 520.

medical schools of the University of Chicago are not operated under the promotion by class system but on an individual plan making it impossible for the schools to report their students in this manner and accordingly they are not included in the figures by classes, but their enrolment is included in the total. Estimates, however, have been included in the figures for 1930-1931 and for the years 1933-1934 and 1934-1935; and in 1935-1936 the enrolment for Duke University also was omitted. At the School of Medicine of the Division of the Biological Sciences of the University of Chicago there were 297 students and at Rush Medical College 223, a total of 520. The fifth year can be spent in intern or research work. There were 265 fewer students enrolled than in 1937-1938, 896 fewer than 1936-1937 and 1,667 less than in 1934-1935. The freshman enrolment decreased thirty-seven, the sophomore enrolment sixty-five, juniors thirty-nine and seniors 115, while those interning or engaged in research increased twenty. These figures are exclusive of the figures for the two schools referred to.

STUDENTS LEAVING SCHOOL DURING FIRST TWO YEARS

Of the 6,356 students selected for the freshman class for the session 1934-1935, it is interesting to note that 898 failed or for other reasons did not undertake sophomore studies and further that 1,216 had dropped out by the end of the second medical year. A comparison of the figures for 1934-1935 with those of

1936-1937 is made inasmuch as those entering in the former year would be completing their preclinical course in the latter year. These data are shown below.

Class Entering 1934	Class Entering 1936
Freshman enrolment	5,910
Junior enrolment	4,947
Loss during 1st 2 years....	963
253 fewer students lost during first two years by the class entering in 1936.	

While 446 fewer freshmen were enrolled in 1936-1937 than in 1934-1935 there were also 253 fewer students who had discontinued their course by the end of the second year. From these figures it is clear that a decrease in the size of the entering class does not mean a corresponding reduction of the number of students in the clinical years. Further, the failure of approximately 20 per cent of the students to continue beyond the second year suggests that many of those who were admitted lacked the ability to meet the exacting requirements of the medical curriculum. Decreases in the entering classes since 1934-1935 may indicate a more careful selection of students which will result in a smaller number dropping out before the beginning of the junior year and a larger percentage of the class pursuing their course to graduation.

NEGRO STUDENTS AND GRADUATES

Negro students enrolled in medical schools in the United States and Canada for the session 1938-1939 are recorded by classes in table 18. Totals for the

session 1937-1938 are shown for comparison. For the last session there were 350 students and sixty-nine graduates. The total number of students for 1938-1939 was twenty-two fewer than for the session 1937-1938, but there were eight more graduates than the previous year. The only medical school for Negro youth, Meharry Medical College, matriculated 183 students and had thirty graduates. At Howard University College of Medicine they comprise a majority of those in attendance and for this session 122 of a class of 129

and twenty-eight of the thirty graduates were Negroes. These two schools graduated 84 per cent of the Negro students. Nine other schools graduated eleven. In twenty schools in the United States, exclusive of Meharry and Howard, forty-one students were enrolled. There were four Negroes in two Canadian schools. The enrolment by classes in all schools was first year

112, second year eighty-seven, third year eighty-four and fourth year sixty-seven, a total of 350.

According to figures computed from the 1938 American Medical Directory, there were 3,392 Negro physicians in the United States.

MEDICAL SCHOOL FEES

In table 19 the eighty-seven medical schools of the United States and Canada, including those offering courses in the basic medical sciences, have been grouped according to the tuition fees charged. To arrive at the figures listed, an average was computed of the resident fees for each school. Three schools have fees under \$100. These were the Universities of North Dakota, Oklahoma and Texas. Fifteen schools had fees over \$500, namely College of Medical Evangelists, Yale, George Washington, Johns Hopkins, Tufts, Columbia, Cornell, Long Island, New York Medical College, New York University, Syracuse, Buffalo, Hahnemann, Pennsylvania and Pittsburgh. Thirty schools in the United States and five in Canada made an additional charge for nonresidents ranging from \$37.50 each year by the University of Illinois College of Medicine to \$400 exacted by Louisiana State University. In 1938 there were four schools in the first bracket under \$99, nine had fees of from \$100 to \$199, twenty-three from \$200 to \$299, sixteen from \$300 to \$399, twenty-two from \$400 to \$499 and thirteen over \$500.

The lowest nonresident fee in the United States was \$37.50. One school in Canada has a nonresident fee of \$5 for the first year and \$10 for the second, third and fourth years. Fourteen schools in the United States and Canada have a nonresident fee of \$99 or less, seventeen have fees between \$100 and \$199, seven have fees from \$200 to \$299 and two have fees of \$300 and \$400 respectively.

The average resident fee charged in medical schools in the United States was \$353, whereas in 1938 it was computed at \$342.

CITIZENS OF THE UNITED STATES ENROLLED IN FACULTIES OF MEDICINE ABROAD

An inquiry into the number of citizens of the United States studying medicine in faculties of medicine abroad has been carried on by the Council on Medical Education and Hospitals since 1931, when it became evident that great numbers were going to Europe to pursue medical courses. It has been almost impossible to obtain figures for the session 1938-1939. Returns were received from forty-four institutions from which there were 680

students and 142 graduates. These figures are undoubtedly incomplete and many more citizens of the United States are studying abroad than the figures for 1938-1939 here given would indicate. The enrolment of

TABLE 20.—Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada, 1930-1938

Totals.....	4,103	2,616	36.3

students in foreign countries for each session since 1930-1931, including the incomplete figures for 1938-1939, are shown in table 21. The largest numbers were enrolled in Austria, Germany, Italy, Scotland and Switzerland.

Education Department in January 1939 directed that such registrations cease for all students hereafter admitted to these institutions and that the department no longer issue qualifying certificates to American students seeking admission to these schools. The department will continue to recognize, however, those already having received the qualifying certificate and already engaged in study in these schools. The schools referred to are the School of Medicine of the Royal Colleges, Edinburgh; Anderson College of Medicine, Glasgow; St. Mungo's College Medical School, Glasgow, and the Schools of Surgery, Royal College of Surgeons in Ireland, Dublin.

Data were also published in the State Board Number 5 indicating the requirements of candidates for medical licensure holding credentials from medical schools outside the United States and Canada. In order to qualify for licensure, many of the foreign graduates are seeking or are serving internships in approved hospitals. In 1938, 149 approved hospitals in twenty-nine states reported a total of 312. The Council has adopted the following resolution in an effort to assist hospitals in solving the perplexing problems asso-

* Incomplete figures.

A study is also being carried on of the license record of foreign physicians.⁵ Table 20, recording the number of graduates of foreign medical faculties examined by licensing boards in the United States in nine years and the percentage failing, is of interest. This table makes no differentiation between United States citizens and those foreign born.

The figures indicate that the greatest number were enrolled in the so-called extramural schools of Ireland and Scotland. As a result of an inspection made of these schools in November 1938, the New York State

ciated with the selection of graduates from foreign schools:

Resolved, That, when suitable graduates of class A schools in the United States and Canada are not available, hospitals approved for intern training may accept graduates of European universities who have passed parts I and II of the examinations of the National Board of Medical Examiners.

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. No opportunity is afforded for visiting and inspecting such schools, nor are official reports received from them. The Council therefore has no evidence on which to base a rating.

GRADUATE MEDICAL EDUCATION

Continuation Study for Practicing Physicians in the United States: 1938-1939

The House of Delegates of the American Medical Association in May 1939 concurred in the opinion that "The attention of the constituent state societies of this Association should be called to the great importance of controlling the direction of programs of postgraduate education. The reference committee herewith recommends that the House of Delegates empower the Council on Medical Education and Hospitals to carry out this purpose."

This recommendation of the Reference Committee on Medical Education emphasized the importance of the present study of graduate medical education which the Council on Medical Education and Hospitals voted to undertake in February 1936. In May of that year the House of Delegates approved the Council's proposed study and in February 1937 the Board of Trustees authorized additional personnel to examine programs of continuation study for practicing physicians in operation in the various states. Since October 1937 thirty-six states and the District of Columbia have been visited and the opportunities for continuing medical education have been reviewed. States included to date are Alabama, Arizona, Arkansas, California, Colorado, Connecticut, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, New Jersey, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, Rhode Island, South Carolina, Tennessee, Texas, Utah, Virginia, West Virginia and Wisconsin. Progress reports of graduate activities in twenty-three states appeared in the Educational Number of *THE JOURNAL*, Aug. 27, 1938, and other reports have appeared from time to time in *THE JOURNAL* during the past year.¹ While subsequent reports will consider the graduate programs of other states, graduate courses in all states are reported herewith.

ORGANIZATION AND ADMINISTRATION

There were 109 opportunities for practicing physicians to engage in continuation study in forty-three states and the District of Columbia. Fifty courses outlined in table 1-A were of an itinerant character, in that the instruction was taken to the physician in or near his local community. Fifty-nine centers listed in table 1-B provided facilities where clinical instruction might be featured over periods of five or more days. With certain exceptions, in the first type of course the instructor does most of the traveling, while in the latter the physician desiring continuation study frequently must leave his community and travel to the center where clinical teaching may be emphasized over longer periods.

There were fifty opportunities for continuation study by physicians near their home communities in thirty-eight states, and forty-three of the courses offered were sponsored either singly or jointly by state medical societies. State boards of health sponsored thirty. Extension divisions of universities and medical schools sponsored seven courses each. Tuberculosis and other special organizations in some states acted as joint sponsors with state medical societies.

Of these fifty itinerant study courses, twenty-four were directed by state medical societies, eighteen by

state boards of health, three by extension divisions of universities, two by tuberculosis organizations and one by the state division for crippled children, and two were jointly directed.

Twenty-two states and the District of Columbia had representative committees in the state society which attempted to provide a continuity and a correlation of all or most of the graduate medical activities of their respective states. Included were such activities as continuation study courses near the home communities of physicians and instruction given in centers where clinical material might be featured, as well as clinical conferences and graduate assemblies. With few exceptions graduate programs have been cooperative enterprises with component medical societies, medical schools, boards of health and other medical and health organizations participating. University extension divisions continued to aid practicing physicians in several states in organizing their graduate programs.

Private and public hospitals and medical schools have contributed their facilities and personnel, which in some states have been indispensable in developing suitable graduate activities.

Continuation study given where there were ample facilities for clinical instruction of five or more days is outlined in table 1-B, in which are listed fifty-nine courses offered in twenty-three states and the District of Columbia. Two other states provided opportunity for physicians to continue professional study elsewhere. Forty-three courses were sponsored by medical schools, including two graduate schools, seventeen by medical and clinical societies and academies of medicine, five by departments of health, three by the Commonwealth Fund of New York and the Bingham Associates Fund, three by hospitals, one by a university center for continuation study, and one by a university extension division. Medical school graduate programs were usually directed by the dean of the school, although sometimes the professor in charge of the course, the chairman of a postgraduate committee or of a department of postgraduate education in the medical school or the director of the division of graduate study would act. Courses sponsored by medical societies were directed by committee chairmen.

METHODS OF INSTRUCTION

States which provided opportunities for physicians to continue professional study near their home communities offered general subjects of medicine in twenty courses, obstetrics and gynecology in twenty-six, pediatrics in twenty-six, general and traumatic surgery in six and special subjects in seventeen.

In twenty-six of these itinerant courses instruction was given for five or more days, in succession or intermittently. In addition to lectures there were clinics, symposiums and conferences included in thirty-three courses. Local hospitals were utilized in thirty-four of the fifty programs. Public buildings, hotels, halls, club rooms and other local facilities were used whenever hospitals were not suitable or available. Approximately one half of the instructors engaged as field clinicians came from within the state where continuation study was offered, and in approximately one half of the

(Continued on page 777)

(Continued from page 773)

courses out of state physicians participated. Of the total, slightly more than one half of the instructors were from medical schools.

Where continuation study featured clinical instruction at one center, such subjects as general medicine, obstetrics, pediatrics and surgery were included. All but five of the graduate programs of five or more days' duration emphasized clinical instruction. Opportunities were given for continuing study of special as well as general subjects of medicine. The following special subjects were included: anesthesia, broncho-esophagology, cardiology, dermatology, forensic medicine, genitourinary surgery, hematology, industrial hygiene, metabolic diseases, ophthalmology, orthopedics, otolaryngology, physical therapy, public health, radiology and venereal diseases. In only nine centers was instruction in preclinical subjects offered over short periods.

The duration of continuation study in which clinical instruction was featured varied from five days to six months or more. Forty-two of the fifty-nine courses in table 1-B lasted from five days to two weeks. Thirteen programs were conducted over periods of four weeks or more. In the remainder the periods of instruction were variable. The time of year in which instruction was given varied considerably. In some of the medical schools it was necessary to accept physicians for short terms of graduate study during vacation periods in order to accommodate them when undergraduate students were not in attendance.

Without exception, something more than didactic lectures was included in the courses given at one center. Laboratory demonstrations, clinics, ward rounds, round table discussions, clinical pathologic and other conferences, symposiums and bedside teaching as well as other practical clinical demonstrations were attempted. Laboratory as well as clinical facilities were utilized. In addition to medical schools which opened their facilities to practicing physicians for short periods of clinical study, use was made of hospitals, medical society buildings, outpatient clinics, health agencies and, in four instances, hotels.

PHYSICIANS' INTEREST IN CONTINUATION STUDY

All continuation courses were open to licensed physicians practicing in or near the community in which the instruction was given. In some only practicing physicians were admitted to the course and, in fifteen of the fifty itinerant continuation courses, membership in county or state medical societies was required. With nine exceptions the approximate yearly attendance was recorded. Registration varied from fifteen at each session in one instance to a total of 1,539 in one state. From 550 to 600 was the median number of practicing physicians who enrolled for all courses of continuation study in each state, excluding brief conferences. In fifteen courses the names of physicians enrolled were published; in some states the names of registrants were reported and filed in the offices of state medical societies. Permanent record systems were being developed in several states. It was observed frequently that physicians once enrolled for graduate instruction often returned for additional courses, especially when they had some voice in electing the kind of educational programs offered.

The success of continuation study programs for practicing physicians is dependent largely on the interest and activity of component medical societies and with few exceptions the best attended and, in the opinion of many physicians, the most useful educational projects

encountered were those actively directed by well organized medical societies. This is especially true in rural communities.

Continuation study featuring clinical instruction particularly should include consideration not only of the physicians anxious to extend their own knowledge of medicine but also of the participation by other physicians who devote, oftentimes without compensation, considerable time and effort to the development of postgraduate programs suitable for their fellows. This applies especially to the organization of clinical material in any continuation course in which clinical instruction is featured. In order to give acceptable instruction in a previously scheduled subject to a group of physicians, it is necessary to have an ample number and diversity of teaching patients available who may be utilized and about whom the discussion may center. On this account, presumably, medical schools, hospitals and outpatient clinics with an abundance of clinical material and with facilities for adequate handling have provided the best opportunities. In the graduate programs listed in table 1-B in which clinical material might be featured, faculty members of medical schools were largely responsible for the instruction.

Eligibility for admission to courses featuring clinical instruction included a doctor of medicine degree in every instance and in some other qualifications in addition. Some medical schools required that physicians be approved by the school before they were accepted for instruction involving the use of clinical material. Programs in public health, hygiene and related subjects such as venereal diseases sponsored or supported in part by health agencies sometimes required that physicians applying for instruction be recommended by state health officers. Medical military courses usually were designed for medical reserve officers of the army and navy, but other practicing physicians also were eligible.

Where clinical material was presented, it was necessary for attendance to be limited to the facilities available. The yearly attendance varied appreciably; 500 or more physicians were accommodated in six centers, from 200 to 500 in five, from 100 to 200 in eight others, while less than 100 were in attendance in the remaining courses listed. Where large numbers of physicians were accommodated, either many varied courses with limited attendance were scheduled, like those offered at Columbia University in New York City, or the instruction simulated that given in clinical conferences, such as the annual program of the Philadelphia County Medical Society. Many variations of these graduate programs were observed. Generally, smaller groups of physicians found greater satisfaction with studies featuring clinical material than did larger audiences before which clinical demonstrations were difficult.

FINANCIAL SUPPORT OF GRADUATE EDUCATION

No registration fees were charged in thirty-seven of the fifty itinerant continuation courses offered; in fourteen, fees varied from \$2 to \$15. Eighteen state medical societies contributed varying amounts. Those reported were from \$1,000 to \$5,000 annually. State boards of health contributed to the financial support of thirty-two courses; federal funds aided fifteen and universities five. The Commonwealth Fund of New York has given substantial financial aid for promoting graduate study in ten states. Tuberculosis associations of two states, a state division of services for crippled children
